Preface to the Fourth Edition

Since 2001 the Ontario Ministry of Health and Long-Term Care (MOHLTC) has provided funding and oversight for a variety of initiatives directed at promoting rational, evidence-based use of blood components, derivatives and alternatives, and reduction of transfusion errors. These included the publication of the First Edition of Bloody Easy in 2003. As the field of Transfusion Medicine is rapidly changing with new evidence to define acceptable practice, subsequent editions produced under the aegis of the Ontario Regional Blood Coordinating Network (ORBCon) in 2006 and 2011, reflected this evolution.

The current Fourth Edition appears as two significant concepts are emerging in the guidance of Transfusion Medicine practice. The first is the approach covered under the rubric of “Patient Blood Management”, which is a discipline designed to optimize patient care for patients who may require transfusion, based on the application of evidence-based, multidisciplinary medical and surgical practices to integrate the best use of transfusion and its alternatives and adjuncts\(^1,2\). The second is the initiative known as “Choosing Wisely\(^b\)” promoted in the U.S. by the American Board of Internal Medicine Foundation (ABIM) (www.abimfoundation.org), and in Canada by the Canadian Medical Association (CMA) (www.choosingwiselycanada.org). “Choosing Wisely” seeks to promote avoidance of wasteful or unnecessary tests, treatments and procedures. An increasing weight of evidence from clinical trials is accumulating to support the clinical benefits of restrictive rather than liberal transfusion policies.

There are several significant changes from the Third Edition. The critical hemoglobin levels to prompt consideration of red blood cell transfusion have been reduced in light of increasing confidence that these recommended levels for restricting transfusion are not resulting in adverse consequences, and, indeed, may in some circumstances result in improved patient outcomes\(^3\). A lack of evidence of clinical benefit from frozen plasma transfusion for mild-marginal coagulopathy as defined by the INR\(^4,5,6\) supports adoption of the “Choosing Wisely” recommendation that an INR of 1.8 or more should replace the convention hitherto of 1.5 or more. In “Adverse Events”, there has been a decline in transfusion transmitted infection and acute lung injury, offset by increasing recognition of circulatory overload, particularly in patients with compromised cardiac function\(^7\). Reference to obsolete practices such as acute normovolemic hemodilution and autologous pre-surgical blood deposit have been removed. The introduction in Ontario of a mandatory request process for IVIG for infusion\(^8\) is intended to reduce inappropriate use of IVIG (about 25-30% of Canadian Blood Services annual budget is for IVIG). A pre-transfusion checklist for physicians (for RBC transfusion orders) has been placed on the back cover (for easy access) to help promote safe ordering practices to reduce the risk of transfusion complications. Finally, a section on the use of Rh immunoglobulin has been added. This and previous editions of Bloody Easy would have been impossible without the dedication, attention to detail and patience of Stephanie Cope, ORBCon Central Office.
Ten Things Physicians and Patients Should Question\textsuperscript{9,10}

1. Don’t transfuse blood if other non-transfusion therapies or observation would be just as effective. Blood transfusion should not be given if other safer non-transfusion alternatives are available. For example, patients with iron deficiency without hemodynamic instability should be given iron therapy.

2. Don’t transfuse more than one red cell unit at a time when transfusion is required in stable, non-bleeding patients. Indications for red blood cell transfusion depend on clinical assessment and the cause of the anemia. In a stable, non-bleeding patient, often a single unit of blood is adequate to relieve patient symptoms or to raise the hemoglobin to an acceptable level. Transfusions are associated with increased morbidity and mortality in high-risk hospitalized inpatients. Transfusion decisions should be influenced by symptoms and hemoglobin concentration. Single unit red cell transfusions should be the standard for non-bleeding, hospitalized patients. Additional units should only be prescribed after re-assessment of the patient and their hemoglobin value.

3. Don’t transfuse plasma to correct a mildly elevated (<1.8) international normalized ratio (INR) or activated partial thromboplastin time (aPTT) before a procedure. A mildly elevated INR is not predictive of an increased risk of bleeding. Furthermore, transfusion of plasma has not been demonstrated to significantly change the INR value when the INR was only minimally elevated (<1.8).
Don’t routinely transfuse platelets for patients with chemotherapy-induced thrombocytopenia if the platelet count is greater than $10 \times 10^9$/L in the absence of bleeding.

A platelet count of $10 \times 10^9$/L or greater usually provides adequate hemostasis. Platelet transfusions are associated with adverse events and risks. Considerations in the decision to transfuse platelets include the cause of the thrombocytopenia, comorbid conditions, symptoms of bleeding, risk factors for bleeding, and the need to perform an invasive procedure.

Don’t routinely use plasma or prothrombin complex concentrates for non-emergent reversal of vitamin K antagonists.

Patients requiring non-emergent reversal of warfarin can often be treated with vitamin K or by discontinuing the warfarin therapy. Prothrombin complex concentrates should only be used for patients with serious bleeding or for those who need urgent surgery. Plasma should only be used in this setting if prothrombin complex concentrates are not available or are contraindicated.

Don’t use immunoglobulin therapy for recurrent infections unless impaired antibody responses to vaccines are demonstrated.

Immunoglobulin (gammaglobulin) replacement does not improve outcomes unless there is impairment of antigen-specific IgG antibody responses to vaccine immunizations or natural infections. Isolated decreases in immunoglobulins (isotypes or subclasses), alone, do not indicate a need for immunoglobulin replacement therapy. Exceptions include genetically defined/suspected disorders. Measurement of IgG subclasses is not routinely useful in determining the need for immunoglobulin therapy. Selective IgA deficiency is not an indication for administration of immunoglobulin.
7 Don’t order unnecessary pre-transfusion testing (type and screen) for all pre-operative patients. Pre-operative transfusion testing is not necessary for the vast majority of surgical patients (e.g., appendectomy, cholecystectomy, hysterectomy and hernia repair) as those patients usually do not require transfusion. Ordering pre-transfusion testing for patients who will likely not require transfusion will lead to unnecessary blood drawn from a patient and unnecessary testing performed. It may also lead to unnecessary delay in the surgical procedure waiting for the results. To guide you whether pre-transfusion testing is required for a certain surgical procedure, your hospital may have a maximum surgical blood ordering schedule or specific testing guidelines based on current surgical practices.

8 Don’t routinely order perioperative autologous and directed blood collection. There is no role for routine perioperative autologous donation or directed donation except for selected patients (for example, patients with rare red blood cell antigen types). Medical evidence does not support the concept that autologous (blood donated by one’s self) or directed blood (blood donated by a friend/family member) is safer than allogeneic blood. In fact, there is concern that the risks of directed donation may be greater (higher rates of positive test results for infectious diseases). Autologous transfusion has risks of bacterial contamination and clerical errors (wrong unit/patient transfused). As well, autologous blood donation before surgery can contribute to perioperative anemia and a greater need for transfusion.
Don’t transfuse O negative blood except to O negative patients and in emergencies for female patients of child-bearing potential of unknown blood group.

Males and females without childbearing potential can receive O Rh-positive red cells. O-negative red cell units are in chronic short supply, in some part due to over utilization for patients who are not O-negative. To ensure O-negative red cells are available for patients who truly need them, their use should be restricted to: (1) patients who are O-Rh-negative; (2) patients with unknown blood group requiring emergent transfusion who are female and of child-bearing age. Type specific red cells should be administered as soon as possible in all emergency situations.

Don’t transfuse group AB plasma to non-group AB patients unless in emergency situations where the ABO group is unknown.

The demand for AB plasma has increased. Group AB individuals comprise only 3% of Canadian blood donors. Those donors who are group AB are universal donors for plasma, thus are the most in-demand type for plasma transfusion. Type-specific plasma should be issued as soon as possible in emergency situations to preserve the AB plasma inventory for those patients where the blood group is unknown.
**Important Notes**

- This booklet is an educational tool to assist in providing care to patients.
- The recommendations do not replace the need to consult an expert in transfusion medicine.
- These recommendations should not be applied rigidly, since they could result in some patients receiving unnecessary transfusions or experiencing adverse effects from under-transfusion.

**Disclaimer:** While the advice and information in these guidelines are believed to be true and accurate at the time of publishing, neither the authors nor the publishers accept any legal responsibility or liability for any errors or omissions in the information provided, or for any of the recommendations made. Any decision involving patient care must be based on the judgement of the attending physician according to the needs and condition of each individual patient.

Overview

Who regulates
- Health Canada regulates blood collection, testing, processing, and distribution.
- Health Canada Blood Regulations require hospitals to follow the national standard (see below) (http://laws-lois.justice.gc.ca/eng/regulations/SOR-2013-178/).

National Standard
- Canadian Society for Transfusion Medicine (CSTM) publishes standards for Hospital Transfusion Services. These standards are consistent with the CSA national standard (www.transfusion.ca).

Who collects
- Canadian Blood Services (CBS), in all provinces and territories except Québec.
- Héma-Québec (HQ) in Québec.

Donor screening
- Donors are screened using:
  - donor questionnaire
  - donor vital signs (temperature, heart rate, blood pressure)
  - donor hemoglobin
- Donor units tested for:

<table>
<thead>
<tr>
<th>DONOR UNITS TESTED FOR</th>

<td>Antibody testing</td>
</tr>
</tbody>
</table>

- All whole blood and apheresis donors at CBS and HQ are unpaid volunteers.
- Plasma for fractionation is screened for parvovirus B19 by nucleic acid testing.

**Whole blood processing**

- Collect 500 mL whole blood.
- Divert the first 40 mL to reduce risk of bacterial contamination from donor skin; the 40 mL are used for donor unit testing.
- Blood is centrifuged and separated into three parts:
  - Red Blood Cells
  - Plasma
  - Buffy coat
- The Buffy coat units from four donors are combined with one plasma unit and further processed to separate the platelets.
- The red blood cell and platelet components are leukoreduced.
Whole blood processing (cont’d)

- Certain groups of patients need irradiated blood components to prevent transfusion-associated graft vs host disease (TA-GvHD).
- CBS and HQ provide irradiated products on demand.
  - Refer to TA-GvHD (see page 71) for list of patient groups that need irradiated blood

**Red Blood Cells and Components: Storage Conditions and Volumes**

*In addition to the 45 minutes required for pre-transfusion specimen testing

HQ provides buffy coat platelets from 5 units of buffy coat. HQ storage limit for platelets is 7 days.

Process for Preparing Blood Components from Donated Units

Step 1 - Whole Blood Separation

- Centrifuged @ 20°C
- Plasma
- Buffy Coat
- RBC

Step 2 - RBC

- RBC
- RBC & Additive
- Leukoreduction

Step 3 - Plasma

- Plasma
- Female Plasma
- Male Plasma
- Fractionation to manufacture albumin and IVIG
- For Transfusion
- Cryo-supernatant
- Cryo-precipitate

Step 4 - Buffy Coat Platelet

- 4 Platelet Buffy Coats
- Male Plasma
- Pool
- Leukoreduction
- Leukoreduced Buffy Coat Platelets

Components
**Informed Consent**

A requirement for transfusion consent is identified as an important priority element to be incorporated into Patient Blood Management Programs.\(^\text{12}\)

**When**
- Discuss the option of a transfusion early enough to allow for a blood alternative(s) to be considered according to the principles of patient blood management.\(^\text{12}\)

**What**\(^\text{13}\)
- Include in your discussion:
  - Description of blood or blood product
  - Benefits
  - Risks
  - Alternatives
- Give your patient the opportunity to ask questions.

**Of note**
- Confirm that you discussed consent with the patient, by noting it in the patient’s chart.
- Complete the informed consent documentation as required at your hospital.
- If transfusion is required, clearly document the reason in the patient’s chart.
- In the special case of Jehovah’s Witnesses, helpful advice may be obtained from their Hospital Information Services 24 hours a day at 1-800-265-0327 (see Appendix B, page 143).
Directed Blood Donations

What
- Directed blood donations are units donated for a specific transfusion recipient.

Who
- Currently in Canada, directed blood donations are only recommended for patients with rare blood cell types.

Where
- Directed blood donations are collected by CBS and HQ.

Of note
- Directed blood donations transfused to family members must be irradiated to prevent TA-GvHD.
- Presently, there are no data to support the concept that directed donors are safer than volunteer donors.
- Directed blood donation programs are logistically complicated to administer and financially more expensive than volunteer donor programs.

Directed blood donations are only indicated in RARE circumstances and should not be collected for routine surgical procedures or for routine top-up transfusions in premature neonates.
Clinical Practice Guidelines

Red Blood Cells

- The American Association of Blood Banks (AABB) recommends adhering to a restrictive transfusion threshold in which the transfusion is not indicated until the hemoglobin level is 70 g/L in hospitalized adult patients who are hemodynamically stable, including critically ill patients.

- The AABB recommends a restrictive RBC transfusion threshold of 80 g/L for patients undergoing orthopedic surgery, cardiac surgery and those with pre-existing cardiovascular disease.

- They also state: “The restrictive transfusion threshold of 70 g/L is likely comparable with 80 g/L, but RAC evidence is not available for all categories of patients.”

Platelets

- Prophylactic platelet transfusion should be given to patients with hypoproliferative thrombocytopenia when the platelet count is $10 \times 10^9$ /L or less.

- For elective central venous catheter placement, a threshold of less than $20 \times 10^9$ /L is recommended for prophylactic transfusion.

- For elective diagnostic lumbar puncture, a threshold of less than $50 \times 10^9$ /L is recommended for prophylactic transfusion.

- For major elective non-neuraxial surgery, a threshold of less than $50 \times 10^9$ /L is recommended for prophylactic transfusion.
- Female children and females of child-bearing age/potential who are Rh(D) negative should probably receive Rh immunoglobulin before, after or within 72 hours of receiving an Rh(D) positive platelet component.

- Males and females who are not of child-bearing potential who are Rh(D) negative and are transfused with Rh(D) positive platelet components probably do not require Rh immunoglobulin.
## When and How to Order Tests

<table>
<thead>
<tr>
<th align="left"><strong>1. Transfusion MIGHT occur during admission</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td align="left"><strong>2. Surgery with &gt;10% risk of transfusion</strong></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th align="left"><strong>1. Transfusion PLANNED</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td align="left"><strong>2. Surgery with &gt;30% risk of transfusion</strong></td>
</tr>
</tbody>
</table>

### Group & Screen
- **GROUP**
  - ABO group
  - Rh (D) group

### Group & Screen & Crossmatch
- **SCREEN**
  - Antibody Screen

- **CROSSMATCH**
  - Antiglobulin Crossmatch OR
  - Immediate Spin Crossmatch OR
  - Computer Crossmatch

---

### Pediatrics
- For infants less than 4 months of age, initial testing must include ABO and Rh(D) group and an antibody screen, using either a specimen from the infant or mother.
- If an unexpected RBC alloantibody is detected in the infant’s or mother’s specimen, it is required that the infant receive RBC units lacking the corresponding antigen(s) or units compatible by antiglobulin crossmatch.
- This regimen should continue until the maternal antibody is no longer detected in the infant’s specimen.

---

**ATTENTION**
Uncrossmatched blood is required if the clinical state precludes waiting for antibody screen and crossmatch (45 minutes).

**CHOOSE WISELY**

The following surgeries should have a transfusion rate of <10% and do not require a group and screen: appendectomy, radical prostatectomy, transurethral resection of the prostate (TURP), hernia repair, single knee replacement, primary total hip replacement, laparoscopic cholecystectomy, isolated laminectomy, upper limb surgery and vaginal hysterectomy.
## Routine Transfusion Medicine Tests

<table>
<thead>
<tr>
<th>Test</th>
<th>Time (Min)</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABO group</td>
<td>5</td>
<td>Patient RBCs tested for A and B antigen.</td>
</tr>
<tr>
<td>Rh (D) group</td>
<td>5</td>
<td>Patient RBCs tested for D antigen.</td>
</tr>
<tr>
<td>Antibody Screen</td>
<td>45</td>
<td>Screens for RBC alloantibodies formed as a result of prior transfusion or pregnancy.</td>
</tr>
<tr>
<td>Antiglobulin Crossmatch</td>
<td>45</td>
<td>Mandatory for patients with RBC alloantibodies. Involves incubation of donor RBCs, recipient plasma/serum, and anti-IgG.</td>
</tr>
<tr>
<td>Immediate Spin Crossmatch</td>
<td>5</td>
<td>Testing involves mixing of donor RBCs and recipient plasma/serum. Used to verify ABO compatibility only.*</td>
</tr>
<tr>
<td>Computer Crossmatch</td>
<td>2</td>
<td>Computer selects appropriate unit (donor units must have been re-tested to confirm ABO group and recipient specimen must be tested twice). Used to verify ABO compatibility only.*</td>
</tr>
</tbody>
</table>

Note: For centers using immediate spin or computer crossmatch, crossmatching red cell units in advance of transfusion/surgery is rarely required unless antibody screen is positive.

* For patients with a negative antibody screen and no history of RBC alloantibodies.
**Checking Identity of Patient**

You must accurately identify the patient at the following times...

1. When collecting a blood specimen:
   - Accurately label each specimen **BEFORE** leaving the patient’s bedside

2. **BEFORE** beginning the transfusion, two clinical team members must:
   - Verify the patient’s identity, by checking the name, date of birth and unique identifier (e.g., hospital file number) on their wristband against the identification on the blood component label before transfusing, and, where possible, also by verbal confirmation. For example, ask: “What is your name?” or “What is your date of birth?”
   - It is also important to ensure the correct component type is being transfused by checking the physician order

**ATTENTION**

Check the patient’s wristband before transfusing!

Failure to check is the major cause of acute hemolytic transfusion reactions.

**Monitoring & Infusion Practices**

How
- RBCs must be transfused through a blood administration filter (170-260 microns).
- RBCs are compatible **ONLY** with normal saline.
Recommended IV access

<table>
<thead>
<tr>

<td>Any size is adequate</td>
</tr>
<tr>
<td>Pediatrics</td>
<td>22-25G</td>
</tr>
<tr>
<td>All components and products – adults and pediatrics</td>
<td>Central venous access devices (CVAD)</td>
</tr>
</tbody>
</table>

Storage

- Only store RBCs in a temperature-controlled refrigerator with continuous temperature monitoring by the transfusion service.
- Freezing or overheating blood may cause hemolysis, and may harm the patient.

Monitor patient

- Check patient’s vital signs:
  - prior to starting each unit
  - 15 minutes after starting
  - at end of transfusion
  - during any transfusion reactions
- Transfuse slowly (50 mL/hr) for the first 15 minutes, where appropriate.
- Monitor the patient closely for the first 15 minutes.

**Pediatrics**

For pediatric patients, transfuse slowly (1 mL/kg/h, up to 50 mL/h) for the first 15 minutes. Usual administration rate is 5 mL/kg/h, up to 150 mL/h.
Monitoring & Infusion Practices (cont’d)

Transfuse
- In non-urgent/non-bleeding/inpatient settings red blood cells should be transfused during daytime hours (for patient safety) and transfused one unit at a time.
- Assess patient prior to ordering another unit.
- Expect a 10 g/L increase in hemoglobin in the non-bleeding adult patient.
- Each unit is usually infused over 2 hours, but always within 4 hours of issue from blood bank.
- Consider a slower rate for patients at risk of circulatory overload and refer to prevention on page 61.
- In massive transfusion, blood should only be warmed using an approved blood warming device.

Pediatrics
Dosage:
- A transfusion of 10 mL/kg of RBC stored in an additive solution is expected to raise the hemoglobin level by approximately 10 g/L.\(^\text{17}\)

Ordering RBCs
- If the patient is not adequately volume resuscitated, the hemoglobin value may be spuriously high OR, in the setting of over hydration, spuriously low.
- A falsely low hemoglobin value may result if test specimen are taken near a site of IV infusion.
- Certain patients require irradiated products. Refer to page 71.
Indications for RBCs

**Acute blood loss**
- Maintain hemoglobin >70 g/L during active bleeding.\(^{18}\)
  - Consider rate of bleeding, hemodynamic factors, evidence of tissue ischemia, institutional speed of blood delivery/laboratory testing in decision about transfusion
  - Ensure prompt blood availability when hemoglobin is <80 g/L
- Consider maintaining a higher hemoglobin level (>80 g/L) for patients with:
  - Unstable or acute coronary syndromes\(^ {19}\)
  - Coronary artery disease\(^ {20}\)
  - Uncontrolled/unpredictable bleeding
- Liberal transfusion practices (hemoglobin >90 g/L) in the setting of gastrointestinal hemorrhage results in a higher rate of re-bleeding and mortality.\(^ {21}\)

**Anemia in critical care and coronary care**
- Consider a transfusion when the patient’s hemoglobin is less than 70 g/L.\(^ {22}\)
- Post-cardiac surgery, there is no benefit to a liberal transfusion strategy (when 75 g/L was compared to 90 g/L there was no difference in 30-day mortality).\(^ {23}\)
- In a patient with an acute coronary syndrome, there is controversy over where to maintain the hemoglobin level.\(^ {14}\)
  - There are insufficient data to recommend maintaining the hemoglobin above some arbitrary level
  - Consider transfusing if there are clear signs of inadequate tissue oxygen delivery in a patient with a low hemoglobin and an acute coronary syndrome
Indications for RBCs (cont’d)

- Unnecessary phlebotomy for laboratory testing is a major contributor to anemia in a critically ill patient.
- Except for patients with unstable coronary artery syndromes, a restrictive transfusion policy (trigger hemoglobin 70 g/L) has proved at least as effective as a liberal transfusion policy for critically ill patients. 
- Recombinant erythropoietin reduces the risk of transfusion in critically ill patients but does not improve mortality, and its use is associated with an increased rate of thrombotic events.

Pediatrics

*Anemia in pediatric critical care*

- In children whose condition is stable in the ICU, a transfusion is not usually required unless the patient’s hemoglobin is less than 70 g/L.
- A restrictive transfusion strategy (trigger hemoglobin 70 g/L) was proven to be as safe as a liberal transfusion strategy (95 g/L).
- This recommendation may not be applicable to neonates under 28 days old, children with severe hypoxemia, hemodynamic instability, active blood loss or cyanotic heart disease as these groups were excluded from this clinical trial.
Several guidelines for small-volume RBC transfusions for newborns have been published in the last decade. Two recent randomized controlled trials came to differing conclusions regarding whether a restrictive strategy was as safe as a liberal strategy. Attention must be drawn to phlebotomy for laboratory testing since it is a significant cause of anemia in neonates. Expert recommendations for transfusion thresholds have been published and are shown in the table below.

<table>
<thead>
<tr>
<th>Respiratory Status</th>
<th>Age of Neonate</th>

<td>Hgb ≤75 g/L</td>
</tr>
</tbody>
</table>

Delayed cord clamping in premature neonates reduces morbidity including risk of transfusion.
**Indications for RBCs (cont’d)**

**Perioperative patients**

- Manage patients undergoing elective surgery preoperatively, intraoperatively, and postoperatively with strategies to minimize the need for RBCs\(^18\) (see pages 86-96).
- Administer RBCs one unit at a time in non-urgent settings.\(^{35,36}\)
- Assess patient prior to transfusing additional units (clinical exam and hemoglobin level).\(^{35}\)
- For orthopedic patients with cardiovascular disease, post-operative transfusion for symptomatic anemia or hemoglobin of less than 80 g/L does not increase adverse outcomes or delay recovery compared to a transfusion trigger of 100 g/L.\(^{37}\)
- Follow guidelines for perioperative patient:

<table>
<thead>
<tr>
<th>HEMOGLOBIN</th>
<th>RECOMMENDATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;90 g/L</td>
<td>Likely inappropriate except in exceptional circumstances.</td>
</tr>
<tr>
<td>70-90 g/L</td>
<td>Likely to be appropriate if there are signs or symptoms of impaired oxygen delivery (e.g., tachycardia, hypotension, cardiac ischemia, syncope, pre-syncope).</td>
</tr>
<tr>
<td>&lt;70 g/L</td>
<td>Likely to be appropriate.</td>
</tr>
<tr>
<td>&lt;60 g/L</td>
<td>Transfusion recommended(^{38})</td>
</tr>
</tbody>
</table>

- Young patients with low risk of ischemic cardiovascular disease can sometimes tolerate greater degrees of anemia.
- Patients with chronic iron deficiency may often be better managed with IV or PO iron alone. (PO iron works very well in children with iron deficiency anemia and Hgb level as low as 30 g/L in the absence of concerning symptoms of anemia and assurance of reliable follow-up.)

---

**CHOOSE WISELY**

Before recommending red blood cell transfusion for the management of anemia, the possibilities for reversal of anemia by non-transfusion treatment should be thoroughly examined.

**ATTENTION**

RBCs: One unit at a time.
Chronic anemia\(^{39,40}\)

- Administer transfusions only when alternatives do not exist or have failed.\(^{18}\)
- Administer RBCs at intervals to maintain the hemoglobin just above the lowest concentration that is not associated with symptoms of anemia.\(^{18}\)
- Assess patients that are expected to have long-term transfusion dependent survival for iron overload.
- Chelation therapy should be considered in patients who are iron-overloaded, transfusion dependent, and who have a life expectancy of more than one year.
- Iron overload is typically present after 20 units of RBCs (patients with a significant component of ineffective erythropoiesis and upregulation of iron absorption may become iron overloaded more quickly).
- Monitor serum ferritin and transferrin saturation: tissue iron overload is likely if ferritin >1,000 ug/L and transferrin saturation >75%.\(^{39}\)
- Desferrioxamine, deferasirox, and deferiprone are available agents for iron chelation, with target ferritin between 500 and 1,000 ug/L, and appropriate monitoring for drug toxicity (refer to package insert).
A Basics

- **Platelets come in 3 forms:**
  - Pool of 4 units of buffy coat derived platelets (pools of 5 in Québec)
  - Single donor (collected by apheresis)
  - HLA-matched single donor (for patients with HLA-alloimmunization and refractory to random donor platelets)

- In non-bleeding patients, the risk of spontaneous hemorrhage is low when platelet count is greater than $10 \times 10^9/L$.

- In Canada, all platelet products are tested for bacterial contamination which lowers but does not eliminate the risk of sepsis.

- Platelet transfusions may be associated with higher odds of arterial thrombosis and mortality among TTP and HIT patients.\(^{41}\)

B Monitoring & Infusion Practices

**How**

- Buffy coat derived pooled platelets from multiple donors or single donor apheresis platelets are supplied.

- Platelets must be transfused through a blood administration filter (170-260 microns).

- Fresh blood administration filter preferred.

- Platelets are compatible ONLY with normal saline.
What
- ABO/Rh-identical platelets are preferred, but ABO/Rh non-identical platelets may be transfused when ABO/Rh-identical platelets are not available.
- Rh negative females of childbearing potential require Rh immunoglobulin (RhIG) when Rh positive platelets are transfused to avoid formation of anti-D antibody.
  - Each platelet pool contains up to 0.5 mL of RBCs
  - Each 120 ug of RhIG covers 12 mL whole blood (6 mL RBC) and lasts approximately 21 days
- RhIG is not recommended for males, and females of non-childbearing potential, because risk of immunization from platelets is low (about 1%) and passive anti-D complicates compatibility testing and may delay transfusion.

Storage
- Platelets must be stored at 20-24 ºC (room temperature) with constant mixing to preserve platelet function.
- Do not refrigerate. Inadvertently “chilled” platelets will be rapidly cleared by hepatic macrophages.

**ATTENTION**

Do NOT put platelets in red cell coolers or in the refrigerator.

**Pediatrics**

**Dose:**
- Children and neonates: 10 mL/kg up to a maximum of 1 pool of platelets.
Monitor patient
- Check patient’s vital signs:
  - prior to starting
  - 15 minutes after starting
  - at end of transfusion
  - during any transfusion reactions
- Transfuse slowly (50 mL/hr) for the first 15 minutes, where possible.
- Monitor the patient closely for the first 15 minutes especially for signs of bacterial sepsis.
- Each dose of platelets should increase the patient’s platelet count at 1 hour by at least 15-25 x 10^9/L. *

Transfuse
- Recommended infusion time is 60 minutes per dose (maximum infusion time 4 hours).

Follow-up
- Outpatients with hypoproliferative thrombocytopenia should have a post-transfusion platelet count every 3-5 platelet transfusions to ensure early detection of HLA-alloimmunization.
- Obtain post-transfusion platelet counts (10-60 minutes) after infusion if patient suspected to be refractory (poor increments at 24 hours) to ensure adequate replacement and recognition of platelet refractoriness. *
  - A platelet increment of <7.5 x 10^9/L suggests refractoriness and requires investigation.
- If increments in platelet count are NOT adequate, special measures are required. Refer to the algorithm on page 31.

* References: 44, 45
PLATELET REFRACTORINESS MANAGEMENT ALGORITHM \(^{44,46}\)

**Post-transfusion increment in platelet count \(<7.5 \times 10^9/L\)**

- **No**
  - Refractoriness not present
  - Continue use of pooled donor platelets
  - Monitor post-transfusion platelet count

- **Yes**
  - Use ABO identical platelets
  - Platelet count increment \(<7.5 \times 10^9/L\)

**Consider, and where present, manage other causes of refractoriness. If absent, test for HLA antibodies**

- **Yes**
  - Antibodies present
  - Determine patient’s HLA type
  - Select HLA-compatible apheresis donor and supply single donor irradiated platelets

- **No**
  - Continued poor responses
  - Post-transfusion increment in platelet count \(>7.5 \times 10^9/L\)
  - Seek transfusion medicine consultation*  

* Consult Blood Centre physician where no hospital transfusion medicine physician available.

### CHOOSE WISELY

Don’t transfuse platelets in the following situations:

- Platelet count above 10 x 10⁹/L with no bleeding in anticipation of a drop to less than 10 x 10⁹/L
- For patients with ITP without major hemorrhage, even when platelet count <10 x 10⁹/L
- For patients undergoing procedures more than 6 hours later (give as close to procedure as feasible)
- For minor procedures with platelet counts >20 x 10⁹/L (e.g., paracentesis or thoracentesis)
Frozen plasma (FP) can be derived from two sources:
- Whole blood donor plasma (290 mL)
- Apheresis donors (290 or 500 mL)
  - large apheresis units (500 mL) are equivalent to 2 units of random donor plasma

Notes:
- ‘Frozen plasma’ (FP) is frozen within 24 hours of collection and ‘Apheresis Fresh Frozen Plasma’ (FFPA) is frozen within 8 hours.
- The factor VIII is slightly lower in FP but this is not clinically significant. All other coagulation factor levels are the same in FP and FFPA, and the 2 products can be used interchangeably.
- FP and FFPA contain 400-900 mg fibrinogen per 250 mL equivalent (4 units of FP contain approximately 2.5 g of fibrinogen).
Monitoring & Infusion Practices

How
- Frozen plasma must be transfused through a blood administration filter (170-260 microns).
- FP is compatible ONLY with normal saline.

Dose
- Small adult: 3 units (10-15 mL/kg).
- Large adult: 4 units (10-15 mL/kg).
- Pediatric: 10 to 20 mL/kg.

When
- The recommended infusion time is 30-120 minutes per unit (maximum time 4 hours).

Storage
- Frozen plasma is kept frozen for up to one year.
  - Once thawed, plasma can be stored at 1-6 °C for 5 days.
- After issue, FP and FFPA should be administered within 4 hours.
  - The biological half-life of plasma coagulation proteins is different for each protein:
    - 3-6 hours for factor VII
    - 8-12 hours for factor VIII
    - 2-3 days for factors II and XI

Monitor patient
- Check patient’s vital signs:
  - prior to starting
  - 15 minutes after starting
  - at end of transfusion
  - during any transfusion reactions
- Transfuse slowly (50 mL/hr) for the first 15 minutes, where possible.
- Monitor the patient closely for the first 15 minutes.
- If clinically indicated, the PT/INR and PTT should be checked after infusion (10-60 minutes).

ATTENTION
The effective half-life of FP is measured in hours. Administer immediately before planned procedures.

ATTENTION
Patients receiving plasma are at high risk for Transfusion-Associated Circulatory Overload (TACO)!
Indications for Frozen Plasma

To determine if FP is indicated for abnormal coagulation test results, the cause of the elevation must be determined (i.e., liver disease vs. warfarin effect vs. single factor deficiency). See Section 4 of Bloody Easy Coagulation Simplified for details. The reasons for this are as follows:

1. There are numerous replacement options and the correct one must be selected for the patient (i.e., FP vs. Prothrombin Complex Concentrates (PCC) vs. single factor concentrate).
2. Warfarin effect and vitamin K deficiency can often be managed with intravenous/oral vitamin K alone.
3. Patients with liver disease have preserved thrombin generation despite elevated INR levels and often do not need correction of the abnormality before procedures.
4. Patients with isolated high PTT (and normal INR) are managed with strategies other than FP.
5. Patients on anticoagulants are never appropriately managed with FP.

1. Bleeding or prior to a significant operative procedure in patients with INR, PT or PTT 1.8 times normal or greater due to multiple factor deficiency when no coagulation factor concentrates or other alternative therapies are available.

- Repeating INR/PT/PTT after infusion of FP may be beneficial to ensure that replacement is adequate.

ATTENTION

FP is NOT indicated or required when INR <1.8 as coagulation factor levels are adequate for hemostasis.

ATTENTION

IV Vitamin K works faster than oral.

ATTENTION

FP is NOT indicated or effective for reversal of heparin, low molecular weight heparin, rivaroxaban, dabigatran, apixiban or edoxaban.

CHOOSE WISELY

Don’t transfuse plasma in the following situations:
- Bleeding and INR <1.8
- Procedure and INR <1.8
- INR elevated but patient is not actively bleeding
- Warfarin reversal
- Heparin/LMWH reversal
- Xa or IIa inhibitor anticoagulant reversal
- High aPTT with normal INR
**Note:**\(^{61,62,63,64}\)

- If available, prothrombin complex concentrates (PCCs) should be used for urgent reversal of warfarin therapy or treatment of vitamin K deficiency in a bleeding patient OR a patient requiring an emergency invasive procedure. Vitamin K (5-10 mg i.v.) should also be given. See page 124 in this guide.

- For non-emergent reversal of warfarin or vitamin K deficiency, vitamin K should be used rather than PCCs.
  - For patients without bleeding and INR >10 due to warfarin, 2 mg of oral Vitamin K will bring INR within the therapeutic range over 24-48 hours
  - After intravenous administration, Vitamin K effect can be detected after 2 hours and the INR should be normalized after 6-24 hours
  - SC and IM NOT recommended due to variable absorption: intravenous formulation can be used orally when required

**Pediatrics**\(^{65}\)

**Vitamin K dose:**

- INR >5–9: 1 to 2 mg oral.
- INR ≥9: 5 mg oral.
- Significant bleed in infants and children: 5 mg IV OR 30 mcg/kg IV.
Indications for Frozen Plasma (cont’d)

2. Microvascular bleeding or massive transfusion AND patient’s clinical status precludes waiting 30-45 minutes for INR/PT/PTT results.\textsuperscript{13}

3. Thrombotic thrombocytopenic purpura.

\textbf{ATTENTION}

Ratio based replacement (i.e., 2:1 RBC:FP) with FP not required when patient is expected to need less than 10 RBC units over 24 hours or time allows replacement based on laboratory testing.

<table>
<thead>
<tr>
<th>INR/PT/PTT</th>
<th>Indication (Pediatric and Adult Patients)</th>
</tr>
</thead>
</table>
| 1.8 or greater | Active bleeding or prior to significant operative procedure in patient with multiple coagulation factor deficiency when no coagulation factor concentrates or other alternative are available  
Note: Patients with liver disease have preserved thrombin generation despite elevated INR levels and often do not need correction of the abnormality before procedures |
| Results not immediately available | Microvascular bleeding or massive transfusion AND patient’s clinical status precludes waiting 30-45 minutes for INR/PT/PTT results |
| Any | Thrombotic thrombocytopenic purpura (TTP) |
What
- It is acceptable to use non ABO compatible cryoprecipitate, where required.
- Cryoprecipitate contains factor VIII, factor XIII, fibrinogen, and von Willebrand factor.
  - Each unit of cryoprecipitate contains a minimum of 150 mg of fibrinogen
- 10 units of cryoprecipitate on average contains 4 grams of fibrinogen

How
- Cryoprecipitate must be given through a blood administration filter (170-260 microns).
- Cryoprecipitate is compatible ONLY with normal saline.

Dose
- Adults: 10 units. Pediatrics: 1 unit/10 kg body weight to maximum of 10 units.
- Each dose will increase the fibrinogen by 0.5 g/L in the bleeding patient.67
- Recommended infusion time is 10-30 minutes per dose (maximum infusion time 4 hours).
- Half-life of fibrinogen is about 7 days.
**Indications**

- For bleeding with fibrinogen <1 g/L.\(^{38}\)
- For massive hemorrhage with fibrinogen <1.5-2.0 g/L.\(^{68}\)
- For acute phase of acute promyelocytic leukemia with fibrinogen <1.5 g/L.\(^{69}\)
- Intracranial hemorrhage secondary to treatment with Tissue Plasminogen Activator with fibrinogen <2.0 g/L.
- Treatment of bleeding in patients with von Willebrand disease or Hemophilia A only:
  - when factor concentrates are unavailable (remote geographic region); and
  - DDAVP is unavailable or ineffective

**Alternatives to Cryoprecipitate**

- Fibrinogen concentrates are licensed for congenital hypofibrinogenemia in Canada.
- There is one fibrinogen concentrate available in Canada: RiaSTAP™ (CSL Behring).
- The vials are 1 gram of lyophilized product that is reconstituted in 50 mL of sterile diluent.
- In hospitals where cryoprecipitate can not be provided, it is reasonable to utilize fibrinogen concentrates (adult dose 4 grams equivalent to 10 units of cryoprecipitate).

**CHOOSE WISELY**

Don’t transfuse cryoprecipitate in the following situations:

- DIC with low fibrinogen level in the absence of bleeding or a planned procedure (other than the acute phase of acute promyelocytic leukemia)
- Any congenital bleeding disorder

Reporting

Attention: All transfusion reactions (mild to life-threatening) and transfusion-related errors must be reported to the hospital’s transfusion service (blood bank).

What

- The Transfusion Medicine Laboratory (TML) will investigate, assess and report the event to Transfusion-transmitted injuries surveillance system (TTISS) which will then report to Public Health Agency of Canada (PHAC)*. In Québec, the hospital’s transfusion service reports all transfusion reactions to Québec Hemovigilance System, which then reports to PHAC.

- Component reactions relating to the quality of the product must also be reported to CBS/HQ.

- Plasma derivative reactions related to quality must also be reported to the particular manufacturer.

How

- CBS/HQ and PHAC* reporting forms are available from all hospital transfusion services.
  - Contact your transfusion service for more information
  - It is the transfusion service’s responsibility to submit them to CBS/HQ and PHAC

**Fever**

**MANAGEMENT ALGORITHM**

### Fever (and/or Shaking Chills/Rigors)

- >1 °C increase in temperature
- AND temperature >38 °C during or up to 4 hours post infusion

#### Immediate Management:

1. Stop transfusion and maintain IV access
2. Take patient’s vital signs
3. Re-check identification of patient & blood product
4. Physician assessment required
5. Notify hospital transfusion service (blood bank), even if transfusion restarted or completed

#### Clerical error or serious symptoms?

- Temperature ≥39 °C, hypotension/shock, tachycardia, shaking chills/rigors, anxiety, dyspnea, back/chest pain, hemoglobinuria/oliguria, bleeding from IV sites, nausea/vomiting

BACTERIAL SEPSIS OR CONTAMINATION

ETIOLOGY

Blood components may be contaminated by:

1. Skin commensals from the donor (each venipuncture may result in a small skin plug that may be retained in the donation bag)
2. Unrecognized bacteremia in the donor
3. Contamination from the environment or from handling of the product

Organisms:

- Serious morbidity and mortality occur most frequently with Gram-negative bacteria, but are also reported with Gram-positive skin bacteria
- A number of bacteria have been implicated, including.

</table>

- Bacterial sepsis accounts for at least 10% of transfusion-associated fatalities.
- Bacterial sepsis occurs most frequently with platelets due to their storage at 20-24 °C for preservation of function.
- About two thirds are Gram-positive and one third Gram-negative.
CLINICAL PRESENTATION

- Clinical features of transfusion-associated sepsis may include: 88,91
  - Rigors, fever, tachycardia, hypotension, nausea and vomiting, dyspnea, disseminated intravascular coagulation
- It is usually possible to culture the offending organism from both the patient and the transfused product.
- There may be no immediate clinical signs of bacterial infection after transfusion of bacterially-contaminated platelets, if the bacterial load is small.
  - Delayed presentation of symptoms up to 24 hours post-transfusion reported90

MANAGEMENT89,91

- If transfusion-transmitted bacterial infection is suspected:
  - Stop the transfusion!
  - Notify the hospital transfusion service (blood bank)
    - Hospital transfusion service (blood bank) will notify the supplier so that:
      - other products from the same donor(s) can be quarantined, cultured, and discarded AND
      - any recipients of other products can be identified and followed up
  - Return residual of blood product(s) and tubing (clamped) for culture and gram stain to the hospital transfusion service
  - Collect peripheral blood specimen for blood culture from a different IV site
  - Provide aggressive supportive therapy as appropriate, including broad-spectrum antibiotics
    - DO NOT WAIT FOR RESULTS OF BLOOD CULTURES PRIOR TO STARTING ANTIBIOTIC THERAPY
  - ATTENTION
    Stop transfusion immediately if bacterial infection is suspected.
  - ATTENTION
    Arrange for Gram stain on unit(s) suspected of being contaminated.
  - ATTENTION
    Start antibiotic therapy immediately, do not wait for results of blood cultures.
PREVENTION

- The skin is disinfected at the donation site to reduce bacterial contamination by skin flora.
- The first 40 mL of blood collected is diverted and sequestered in a pouch to reduce risk of transmitting organisms from skin (can be used for infectious agent testing).
- Apheresis and buffy coat platelets are cultured by CBS/HQ prior to issue to hospitals.
- RBCs are stored at 1-6 °C in a monitored blood bank refrigerator.

ACUTE HEMOLYTIC TRANSFUSION REACTION

ETIOLOGY

- Acute hemolytic transfusion reactions may be associated with:
  - ABO-incompatibility
  - Other blood group incompatibilities
    - There are 29 blood group systems and 346 known blood group antigens that may cause incompatibility (in addition to ABO)\(^92\)
    - Rare cases when group O platelets with high titers of anti-A and/or anti-B are transfused to a non-group O recipient\(^93\)
  - ABO-incompatibility:
    - Is due to a clerical error or other error in patient identification
    - HALF of all errors are due to administering properly labelled blood to the wrong patient\(^94\)
    - Other errors are the result of improper labelling of specimens or testing errors

ATTENTION

Keep RBCs in an approved fridge or cooler until immediately prior to transfusion!
RBC alloantibodies (non-ABO):
- Result from patient immunization from a prior pregnancy or transfusion
- Causes of reactions include:
  - Red cell alloantibodies in the patient’s plasma below the level detected by the antibody screen
  - Clerical error during patient antibody screening
  - Failure to detect RBC antibody due to limitations of the laboratory assay
  - Uncrossmatched blood transfused to a patient who is alloimmunized

INCIDENCE
- 1 in 38,000 red cell transfusions are ABO-incompatible due to transfusing the wrong blood to a patient.\(^{94}\)
- Less than 10% of ABO-incompatible transfusions result in a fatal outcome.\(^{94}\)
- Over 50% of patients have no morbidity from an ABO-incompatible transfusion.
- Risk of death correlates with the amount of incompatible blood transfused.\(^{95}\)

CLINICAL PRESENTATION\(^{96}\)
- Most common clinical presentation is:
  - Fever and chills
  - Hemoglobinuria
  - Less common: pain, hypotension, nausea/vomiting, dyspnea, renal failure, DIC
- Fever may be the only presenting sign of an acute hemolytic transfusion reaction.
**MANAGEMENT**

- **Stop the transfusion!**
- Check if there is a clerical error. Check identity of patient vs. patient identity on blood product label.
- Notify hospital transfusion service (blood bank).
- Send specimens to hospital transfusion service to re-check ABO-group.
- Return residual of blood product(s) and tubing (clamped) to the hospital transfusion service.
- Send first post-transfusion urine specimen for urinalysis.
- Provide supportive care.
  - Maintain good urine output
  - Manage DIC and hemorrhage as clinically indicated

**PREVENTION**

- Pay meticulous attention to identifying the patient and labelling the tubes at specimen collection (to ensure that patient is assigned to the correct blood group).
- Pay meticulous attention to verifying the patient’s identity, by checking their wristband, before transfusing.
  - Confirm the patient’s identity (for patients that are conscious) verbally in case the patient’s armband is incorrect (armband errors do occur)
FEBRILE NON-HEMOLYTIC TRANSFUSION REACTION (FNHTR)

ETIOLOGY

- Attributable to:
  - Soluble factors (e.g., cytokines) in the plasma of the component transfused
  - Recipient antibodies, reactive to antigens expressed on cells in the component, usually white blood cells

INCIDENCE

<table>
<thead>
<tr>
<th>Component</th>
<th>Incidence</th>
</tr>
</thead>
<tbody>
<tr>
<td>RBC</td>
<td>1 in 300</td>
</tr>
<tr>
<td>Platelet pool</td>
<td>1 in 20</td>
</tr>
</tbody>
</table>

CLINICAL PRESENTATION

- Fever usually occurs during or up to 4 hours post transfusion.
  - May be associated with chills, rigors, nausea, vomiting and hypotension
- Fever is not always present (i.e., chills, nausea, etc., alone).

MANAGEMENT

- Acetaminophen
- Meperidine (Demerol®) 25-50 mg IV may be effective for severe rigors if the patient has no contraindications to meperidine.

PREVENTION

- Pre-medications with acetaminophen and diphenhydramine has not been shown to be effective in preventing FNHTR.99,100
- In patients with significant and recurrent FNHTR, the following measures have been used but efficacy is unproven:
  - Acetaminophen, corticosteroids, fresh components, plasma-depleted components, washed red blood cells (washing platelets results in 50% loss of platelets)
- Antihistamines are not effective.

ATTENTION

- Fever is not a contraindication to commencing a blood transfusion!
- Meperidine has numerous serious drug interactions. Consult pharmacy if the patient is on SSRIs, MAOIs, antibiotics, antifungals, or medications for seizures.
Dyspnea
(Anaphylaxis is described under Allergic Reactions/Anaphylaxis)

MANAGEMENT ALGORITHM

**Dyspnea**

---

**Immediate Management:**
1. **Stop transfusion** and maintain IV access with 0.9% saline
2. Take patient’s vital signs
3. Re-check identification of patient & blood product
4. Physician assessment required
5. Notify hospital transfusion service (blood bank)
6. Return clamped blood unit with tubing attached

---

**Consider:**
- **TRANSFUSION-RELATED ACUTE LUNG INJURY (TRALI)**
- **TRANSFUSION-ASSOCIATED CIRCULATORY OVERLOAD (TACO)**
- **ANAPHYLAXIS**
  - If TRALI is suspected, notify hospital transfusion service (blood bank) so that special donor and recipient testing can be performed
  - Order STAT chest X-ray
  - Oxygen, diuretics and supportive care as required, depending on type of reaction
TRANSFUSION-RELATED ACUTE LUNG INJURY (TRALI)\textsuperscript{101,102}

DEFINITION OF ACUTE LUNG INJURY (ALI)
- Acute onset.
- Hypoxemia:
  - PaO\textsubscript{2}/FiO\textsubscript{2} <300 mmHg; OR
  - Oxygen saturation is <90\% on room air; OR
  - Other clinical evidence
- Bilateral lung infiltrates on the chest radiograph.
- No evidence of circulatory overload.

DEFINITION OF TRALI
- In patients with no evidence of ALI prior to transfusion, TRALI is diagnosed if:
  - New ALI is present
  - It occurs during or within 6 hours of completion of transfusion
  - There are no other risk factors for ALI (see orange box to the right)

DEFINITION OF POSSIBLE TRALI
- In patients with no ALI prior to transfusion, possible TRALI is diagnosed if:
  - New ALI is present
  - It occurs during or within 6 hours of completion of transfusion
  - There are one or more risk factors for ALI (see orange box to the right)

RISK FACTORS FOR ACUTE LUNG INJURY
Predisposing factors for ALI include:
- Direct Lung Injury
  - Aspiration
  - Pneumonia
  - Toxic inhalation
  - Lung contusion
  - Near drowning
- Indirect Lung Injury
  - Severe sepsis
  - Shock
  - Multiple trauma
  - Burn injury
  - Acute pancreatitis
  - Cardiopulmonary bypass
  - Drug overdose
ETIOLOGY

Presently not fully defined. Two postulated mechanisms have been implicated:102,103

1. Antibody-mediated: Passive transfer of HLA or granulocyte antibodies from donor to blood product recipient; or, less commonly, HLA or granulocyte antibodies in the recipient (antibodies detected in donor or recipient in 80% of cases).104,105
   - Antibodies are most common in multiparous female donors as a consequence of prior pregnancies
2. Neutrophil priming hypothesis: Biologic response modifiers such as biologically active lipids in the transfused component may induce TRALI in a susceptible patient.106

INCIDENCE

True incidence of this syndrome is unknown; two separate hospital-based reports estimate TRALI at 1 in 1,200 to 5,000 plasma-containing transfusions, respectively.104,107 (Both studies were performed before TRALI reduction measures.)

The incidence of TRALI has decreased by approximately half with implementation of TRALI reduction measures with SHOT and American Red Cross reporting large reductions in cases (see Prevention).73,108

TRALI is known to be under-diagnosed and under-reported.
PRESENTATION
- Dyspnea, hypoxemia, fever and hypotension.
- Chest X-ray reveals interstitial and alveolar infiltrates (pulmonary edema), without elevated pulmonary pressures.
- Usually occurs with transfusion of RBCs, platelets and plasma, but rarely with other blood products (including cryoprecipitate and IVIG).
- Almost always within the first 1-2 hours after the start of transfusion but can be delayed for up to 6 hours.\textsuperscript{104}
- Usually resolves in 24-72 hours.
- 72\% of reported cases required mechanical ventilation and death occurs in 5-10\% of patients experiencing a TRALI reaction.\textsuperscript{104}
- Milder forms of TRALI are thought to exist and may present as transient hypoxia.\textsuperscript{109}
- Acute transient leukopenia may be observed after a TRALI reaction.\textsuperscript{110}

Chest X-ray of a patient before and during an episode of transfusion-related acute lung injury (TRALI)
MANAGEMENT

- Supportive care, including mechanical ventilation when clinically indicated.
- Diuretics and steroids are not believed to be useful in treating TRALI.111
- Accurate reporting to hospital transfusion service is critical to identify implicated donors and prevent TRALI in other recipients.
- Patient and donor testing should be arranged through the hospital transfusion service (testing performed through CBS/HQ).

PREVENTION

- Adherence to evidence-based transfusion guidelines.
- Component strategies to reduce TRALI include:
  - Plasma for transfusion predominantly from male donors
  - Buffy coat platelet pools suspended in male plasma
  - Plateletpheresis collected from male donors or never pregnant females
- Deferral of donors confirmed to be implicated in an episode of TRALI, and with either antibodies or implicated in multiple episodes.
TRANSFUSION-ASSOCIATED CIRCULATORY OVERLOAD (TACO) 112

ETIOLOGY
- Circulatory overload results from:
  1. Impaired cardiac function, **AND/OR**
  2. Excessively rapid rate of transfusion

INCIDENCE
- Current estimate of the frequency of TACO range from 1 in 700 to 8% of transfusion recipients.7
- Patients over 70 years of age, infants, and patients with severe euvoletic anemia (hemoglobin <50 g/L), renal impairment, fluid overload, and cardiac dysfunction are particularly susceptible.

CLINICAL PRESENTATION
- Clinical presentation includes: dyspnea, orthopnea, cyanosis, tachycardia, increased venous pressure, and hypertension.

MANAGEMENT
- Interrupt the transfusion.
- Administer oxygen and diuretics as needed.
- Chest x-ray.
- Consider restarting transfusion at a reduced infusion rate if clinical status allows and product still viable.

ATTENTION
TACO is the most common cause of death from transfusion!
**PREVENTION**

- Pre-transfusion assessment is important to identify patients at risk and management should be adjusted accordingly.
- Preventative measures include:
  - Avoid transfusing more than one unit at a time
  - Transfuse over longer periods (maximum 4 hours)
  - Pre-emptive diuretics
  - Components can be split into smaller aliquots to further reduce the speed of infusion without wasting product or increasing donor exposure

**ATTENTION**

The following are risk factors for TACO:
- Age over 70 years
- History of heart failure
- Left ventricular dysfunction
- History of myocardial infarction
- Renal dysfunction
- Positive fluid balance

**ATTENTION**

In patients at risk, avoid transfusing more than one unit at a time.

**CHOOSE WISELY**

Avoid unnecessary transfusion of blood products and maximize the use of alternatives.
Urticaria & Other Allergic Reactions/Anaphylaxis

MANAGEMENT ALGORITHM

Allergic Reaction

A transfusion reaction that may be associated with urticaria, facial edema, airway edema, lower respiratory tract symptoms, hypotension, or shock

Immediate Management:
1. **Interrupt the transfusion** & maintain IV access
2. Take the patient’s vital signs
3. Re-check identification of patient and blood product
4. Physician assessment required
5. Notify hospital transfusion service (blood bank) even if transfusion restarted or already completed

Clerical error, anaphylaxis or serious symptoms?
1. Hypotension
2. Dyspnea/cough
3. Tachycardia
4. Generalized flushing or anxiety
5. Nausea/vomiting
6. Widespread rash >2/3 body

**No**
Consistent with minor allergic reaction
Give diphenhydramine 25-50 mg IV/po
Continue transfusion cautiously
Stop transfusion if patient develops any of the above symptoms

**Yes**
DO NOT RESTART TRANSFUSION
• Notify the patient’s physician **STAT**
• Notify the hospital transfusion service (blood bank) immediately
SUSPECT ANAPHYLACTOID REACTION/ANAPHYLAXIS
ANAPHYLAXIS

ETIOLOGY\textsuperscript{113}

- Vast majority of anaphylactic reactions are unexplained.
- The following mechanisms have been implicated in anaphylaxis/anaphylactoid reactions:
  - Anti-IgA in an IgA deficient recipient
  - Antibodies to polymorphic forms of serum proteins (IgG, albumin, haptoglobin, α-1-antitrypsin, transferrin, C3, C4, etc.)
  - Transfusing an allergen to a sensitized patient (e.g., penicillin, ASA, etc., consumed by donor)
  - Passive transfer of IgE (to drugs, food)
- 1 in 500 blood donors are IgA deficient (IgA < 0.05 mg/dL), and 1 in 1,500 blood donors have anti-IgA, but most are NOT at risk of an anaphylactic transfusion reaction (reasons are not clear at this time).\textsuperscript{114}
  - Anti-IgA as a cause of anaphylaxis from transfusion has recently been called into question due to the lack of evidence implicating IgA deficiency in this entity.\textsuperscript{115}
- Haptoglobin deficiency is not uncommon in Asian patients (1 in 1,000) and has been associated with anaphylactic reactions.\textsuperscript{116}

INCIDENCE

- Transfusion-associated anaphylactic shock is rare.\textsuperscript{117}
- Anaphylaxis accounts for approximately 5% of transfusion associated fatalities.\textsuperscript{86}
CLINICAL PRESENTATION

- Reactions usually begin within 1 to 45 minutes after the start of the infusion.
- Cutaneous reactions (urticaria) are present in the majority of anaphylactic and anaphylactoid reactions.
  - When hypotension and hypoxia follow transfusion, examine skin for urticaria (e.g., under drapes in operating room)
- Anaphylactic/anaphylactoid reactions are associated with upper or lower airway obstruction (symptoms may include hoarseness, stridor, wheezing, chest pain, dyspnea, anxiety, feeling of impending doom), hypotension, gastrointestinal symptoms (nausea, vomiting), rarely death.
- Potentially life-threatening.

TREATMENT

- Stop the transfusion! Do not restart.
- If severe urticarial reaction involving $>2/3$ body surface area: Stop the transfusion and do not restart. Administer 25-50 mg diphenhydramine.
- Anaphylaxis: Promptly administer epinephrine, corticosteroids, diphenhydramine, vasopressors, and supportive care as required.
- Provide ventilatory support as indicated clinically.

PREVENTION OF RECURRENT ANAPHYLAXIS

- Pre-medication with intravenous steroids and diphenhydramine.
- If a patient is found to be IgA-deficient with anti-IgA, the following products are recommended:
  - IgA-deficient blood products from IgA deficient donors, available from CBS/HQ
  - Washed RBCs (2L normal saline in 6 wash cycles) or platelets

ATTENTION

- Stop the transfusion if patient has anaphylactic reaction. Do not restart.
- Epinephrine should be readily available whenever transfusion is carried out.
MINOR ALLERGIC REACTION – URTICARIA

ETIOLOGY
- Unclear, but relates to factors in the plasma portion of the component.

INCIDENCE
- Urticarial reactions are commonly encountered: 0.42% of red blood cell, 3.04% of platelet and 3.15% of plasma transfusions.119

CLINICAL PRESENTATION
- One urticarial lesion to widespread urticarial lesions.
- May be associated with pruritis, erythema, flushing, or mild upper respiratory symptoms (cough, wheezing), nausea, vomiting, abdominal cramps, or diarrhea.

MANAGEMENT
- Interrupt the transfusion.
- Give diphenhydramine 25-50 mg po or IV depending on severity of the reaction.
- Restart the infusion slowly only if:
  1. The urticarial rash involves <2/3 of the body surface area; and,
  2. There are no associated symptoms suggesting a severe allergic reaction.

PREVENTION
- If the urticarial reactions are recurrent, the following precautionary measures may be used although their efficacy is unknown:
  - Pre-medicaiton with diphenhydramine and/or corticosteroids
  - Plasma depletion of RBCs or platelets
  - Washed RBCs or platelets

ATTENTION
Interrupt transfusion.
Give diphenhydramine.
Restart transfusion slowly.
Hypotension

MANAGEMENT ALGORITHM

Hypotension

>30 mmHg drop in systolic or diastolic blood pressure*

Immediate Management:
1. Stop the transfusion and maintain IV access
2. Take patient’s vital signs
3. Re-check identification of patient & blood product
4. Consider differential diagnosis

Consider:
1. Acute hemolytic transfusion reaction
2. Bacterial sepsis
3. Severe febrile non-hemolytic transfusion reaction
4. Bradykinin mediated hypotension
5. Transfusion-related acute lung injury
6. Anaphylaxis

No
unrelated to transfusion
Possibly resume transfusion
after reassessing

Yes

Do not restart transfusion. Refer to appropriate sections.

* Definition refers to adult patients only

Pediatrics

Hypotension in children is defined as:

- Infants, children and adolescents (1 year to less than 18 years old):
  - Greater than 25% drop in systolic BP from baseline.
- Neonates and small infants (less than 1 year old OR any age and less than 12 kg body weight):
  - Greater than 25% drop in baseline value using whichever measurement is being recorded (e.g., mean BP).
BRADYKININ MEDIATED HYPOTENSION

ETIOLOGY
- Bradykinin is believed to play a major role in generating hypotension.
- Angiotensin-converting enzyme is the main enzyme responsible for degradation of bradykinin.
  * Some individuals have a genetic polymorphism resulting in a decrease in bradykinin degradation

INCIDENCE
- Unknown.

CLINICAL PRESENTATION
- Majority of hypotensive reactions occur with platelet transfusions.
- Of reported cases, over half of the patients were on ACE inhibitors.
- Other symptoms may be present, including dyspnea, urticaria, nausea, and vomiting.
- Rarely associated with significant morbidity or mortality.

TREATMENT
- Detect early: Monitor the patient for the first 15 minutes and vital signs at 15 minutes.
- Stop the transfusion and do not re-start.
- Provide supportive care, including intravenous fluids.
- Consider acute hemolytic transfusion reaction, sepsis, TRALI and allergic reactions in the differential diagnosis.

PREVENTION
- In cases where ACE inhibitors were implicated, consider (where possible) an alternative anti-hypertensive prior to additional transfusions.
Hemolysis After Transfusion

HEMOLYSIS NOT RELATED TO RBC ALLOANTIBODIES

- Hemolysis may also occur in the following settings and should be considered in the differential diagnosis of hemolysis after transfusion:
  - Use of hypotonic IV solutions with RBC transfusions
  - Medical device-related (e.g., cell saver or blood warmer malfunction)
  - Overheating of RBCs due to improper storage (e.g., RBCs placed on radiator)
  - Freezing of RBCs (e.g., transport of blood directly on ice or storage in freezer)
  - Transfusion of RBCs under pressure through a small bore needle
  - Transfusion of outdated or near outdated RBCs
  - Non-transfusion-related causes

- Most are benign, but life-threatening hemolysis with severe anemia and renal failure may occur.

DELAYED HEMOLYTIC TRANSFUSION REACTIONS

ETIOLOGY

- Results from the formation of antibodies in the recipient (to transfused red cell alloantigens or from RBC antigen exposure during a prior pregnancy) and below the level of detection on the initial antibody screen testing.

- Commonly implicated antigens are (in order of frequency): E, Jkα, c, Fyα, K.121

- Delayed hemolysis may occur with transfusion-transmitted malaria and babesiosis.
INCIDENCE
- 8% of recipients will have newly formed RBC alloantibodies detected in the first 6 months.\textsuperscript{70}
- 1 in 6715 units of RBCs transfused are associated with a delayed hemolytic transfusion reaction.\textsuperscript{121}

CLINICAL PRESENTATION
- 3 days to 2 weeks after transfusion, the patient presents with hemolytic anemia (low hemoglobin, high bilirubin, reticulocytosis, spherocytosis, high LDH, positive antibody screen, and a positive direct anti-globulin test).\textsuperscript{122}

COMPLICATIONS
- Most are benign, but life-threatening hemolysis with severe anemia and renal failure may occur.

TREATMENT
- Transfuse compatible blood (‘antigen negative’; i.e., if the offending antibody is anti-Jk\textsuperscript{a}, then the transfusion service will provide units that do not carry the Jk\textsuperscript{a} antigen).

PREVENTION
- Avoid RBC transfusions.
- Use of antibody screening methods with maximal sensitivity.
- Notify patient and provide an antibody card for the patient to carry in their wallet.

### Antibody Card

**Special Requirements:**

- **ANTIBODY:** (RBS)
- **ANTI-E**
Cytopenias After Transfusion

TRANSFUSION-ASSOCIATED GRAFT VERSUS HOST DISEASE (TA-GvHD)\textsuperscript{123,124}

**ETIOLOGY**
- TA-GvHD has been reported in immunocompromised patients or in immunocompetent individuals transfused a fresh (<14 day old) haploidentical product. (The risk of an HLA-haploidentical donor in North America is estimated at 1 in 17,700 to 39,000.)\textsuperscript{125,126}
  - A donor who is homozygous for an HLA type (haploidentical), whose blood product is transfused to a recipient who is heterozygous for the same HLA type and a different HLA type places the recipient at risk
    - The donor’s lymphocytes mount a reaction against the non-matching HLA determinants on the recipient’s cells

**INCIDENCE**
- Unknown; there were 13 cases reported in the UK SHOT program from 1996 to 2001; since 2001 there has been one case in 2012 attributed to failure to irradiate maternal blood for an intra-uterine fetal transfusion.\textsuperscript{73}

**CLINICAL PRESENTATION**
- Fever, rash, liver dysfunction, and diarrhea commencing 1-2 weeks post-transfusion followed by pancytopenia later.
- Overwhelming infections are the most common cause of death.
- Mortality is >90%.\textsuperscript{126}
- Diagnosis can be made by biopsy of skin, liver, or bone marrow.
- Confirmation requires documentation of the presence of donor lymphocytes (e.g., HLA typing, short tandem repeat analysis).

**TREATMENT**
- Largely ineffective.
- Survival (which is rare) is attributed to immunosuppressive therapy.
PREVENTION

- For patients at risk (see below), it is critical to irradiate cellular blood components (RBC and platelets).
- To avoid unacceptable high hemolysis (>0.8%) and elevated potassium levels from irradiation, adherence to the Council of Europe’s guidelines is advised. Red cells may be irradiated up to 28 days after collection and should be transfused as soon as possible, but no later than 14 days after irradiation, and no later than 28 days after collection.127,128

PATIENTS REQUIRING IRRADIATED BLOOD129

- Patients with severe T-cell congenital immunodeficiency states
- Intrauterine transfusions (IUT)
- Neonatal exchange transfusions for infants with prior IUT
- Neonatal top-up transfusion if there has been a previous IUT
- Patients with Hodgkin’s lymphoma
- Patients undergoing bone marrow or stem cell transplants
  - It is reasonable to continue providing irradiated products until immunosuppression discontinued
- Recipients of directed transfusions from family members
- Recipients of HLA-matched platelets
- Patients treated with purine analogs (e.g., fludarabine), purine antagonists (e.g., bendamustine), alemtuzumab and anti-thymocyte globulin

- Notify patient in need of irradiated blood and provide a card for the patient to carry in their wallet.
POST-TRANSFUSION PURPURA (PTP) 130

ETIOLOGY

- Transfusion of platelet antigen-positive RBCs, plasma, or platelets to a patient who lacks the same platelet antigen.
  - 75% of cases occur in an Human Platelet Antigen-1b (HPA-1b) homozygous patient who is transfused HPA-1a positive blood products
  - 3% of the North American population are HPA-1b homozygotes, but only 28% appear able to form anti-HPA-1a
- Autologous platelet destruction occurs but the mechanism is unclear.

INCIDENCE

- 1 in 100,000; post-transfusion purpura occurrence among the inpatient U.S. elderly, as recorded in large medicare databases during 2011 through 2012. 131

CLINICAL PRESENTATION

- There are 5 times as many female transfusion recipients with PTP as males, as a consequence of sensitization in a previous pregnancy.
- Occurs post-transfusion at a mean of nine days (range 1 to 24).
- Platelet count is less than $10 \times 10^9$/L in 80% of cases.
- Mortality is 8% and the majority of deaths are from intracranial hemorrhage.
- Transfusions are frequently associated with fever, chills, rigors, and bronchospasm.
- Differentiation from straightforward platelet alloimmunization is problematic.
  - PTP should be considered when a platelet refractory patient fails to respond to HLA-matched platelets
TREATMENT
- Test patient plasma for platelet-specific antibodies (performed at CBS/HQ).
- Thrombocytopenia lasts approximately 2 weeks.
- First-line therapy is IVIG at a dose of 1 g/kg daily for 2 days; the platelet count is expected to increase 4 days after the start of therapy.

PREVENTION
- Patients with PTP should receive antigen-negative RBC and platelet transfusions (washed RBCs do not appear to be safe in this population).

WARNING
- Affected patients (and their relatives) are at risk of neonatal alloimmune thrombocytopenia (NAIT). The family should be tested and counselled regarding both PTP and NAIT.
  - NAIT occurs when a woman has anti-platelet antibodies (usually anti-HPA-1a) and is carrying an antigen-positive fetus; the infant is frequently born with severe thrombocytopenia, and sometimes, intracranial hemorrhage.

ATTENTION
Family members of patients with PTP are at risk of NAIT.

TRANSFUSION-RELATED ALLOIMMUNE THROMBOCYTOPENIA
- Uncommon cause of thrombocytopenia.
- Due to platelet specific donor alloantibodies to patient platelet antigens.\(^{132}\)

TRANSFUSION-RELATED ALLOIMMUNE NEUTROPENIA\(^{133}\)
- Rare cause of neutropenia.
Virus, Parasite and Prion Infections

(Bacterial contamination is described under Fever)

VIRUSES

Risks

- Donating blood in the ‘window period’ – the interval between the time of infectivity and the appearance of detectable disease markers such as specific antibodies or viral nucleic acid sequences.
- Current ‘window period’ estimates are:\textsuperscript{134}
  - 10 days for HIV
  - 8 days for HCV
  - 38 days for HBV
- Figures in chart below are risk per donor exposure: (i.e., 1 unit of RBC).\textsuperscript{135,136}

Cytomegalovirus (CMV):

- Leukoreduced cellular components have a very low residual risk of transfusion transmitted CMV.
- It is unknown if CMV seronegative units have any additional benefit to leukoreduction.
- The estimated residual risk of CMV from leukoreduced red cell and platelet units is 1 in 13,575,000\textsuperscript{137}
An allogeneic stem cell transplant program recently reported on a decade of patients undergoing allogeneic transplant with leukoreduction as the sole strategy without a single patient developing transfusion transmitted CMV.\textsuperscript{138}

The current requirement for residual WBC after leukoreduction is $<5.0 \times 10^6$ WBC/unit.
- For fiscal year 2014/15 the mean monthly residual WBC far exceeded these requirements (data from CBS):
  - Pooled platelet – $0.006 \times 10^6$ WBC/unit (fail rate 0.00%)
  - RBCs – $0.063 \times 10^6$ WBC/unit (fail rate 0.15%)

CMV serology must be drawn before allogeneic transfusions commence, otherwise false positive results may be found due to passive antibody detection.

**West Nile Virus (WNV)**
- No reported cases of transfusion transmitted WNV in Canada since nucleic acid testing of donations began in 2003.\textsuperscript{139}
- Facts about transfusion-transmitted WNV:
  - The virus can be transmitted through RBCs, platelets, plasma, and cryoprecipitate, but not through manufactured blood products (e.g., albumin, IVIG, clotting factor concentrates)
  - The onset of symptoms post-transfusion has ranged from 3 to 13 days (median 7 days)
  - Symptomatic recipients were primarily immunocompromised patients; however, post-partum and post-operative patients have been affected
PARASITES

Chagas Disease
- Chagas Disease is caused by the protozoan Trypanosoma cruzi found predominantly in Central and South America.
- There have been 7 reported cases of transfusion transmitted Chagas in US and Canada, mostly with platelet products.\(^{140}\)
- Since May 2010, at risk donors in Canada are tested for Chagas Disease.
- The current risk of transfusion-transmission is estimated to be 1 in 4 million, based on U.S. data.\(^{141}\)

PRIONS

Variant Creutzfeldt-Jakob Disease (vCJD)
- 4 suspected cases of transfusion-associated transmission have been reported in the U.K.\(^{142}\)
- 1 suspected case of transmission from U.K.-derived Factor VIII concentrate.\(^{143}\)
- At present, high-risk blood donors (resident in the U.K. or France for more than 3 months, or Saudi Arabia for more than 6 months between 1980-1996, or in Europe for more than 5 years between 1980 and 2007) are deferred in Canada.
OTHER TRANSFUSION-TRANSMISSIBLE AGENTS\textsuperscript{140,144,145}

- Other rare infectious agents confirmed to be transmitted by blood components that may cause symptomatic infection include:
  - **Viral** – Parvovirus B19, Hepatitis A and E, Dengue, Chikungunya, Tick-borne encephalitis, Colorado Tick Fever, Human Herpes virus 8, SEN virus, Simian foamy virus and Zika virus
  - **Protozoal** – Malaria, Babesiosis, Leishmaniasis, Toxoplasmosis
  - **Helminthic** – Filariasis
  - **Spirochetal** – \textit{Treponema pallidum} (Syphilis)
  - **Rickettsial** – \textit{R. rickettsii} (Rocky Mountain Spotted Fever), \textit{R. burnetii} (Q fever), Ehrlichia (Ehrlichiosis)

- It is extremely important to report cases of the above infections in transfusion recipients and recent blood donors.
Complications of Massive Transfusion

**Definition**
- More than 10 units of RBCs, or, transfusing more than one blood volume in a 24-hour period.
- Massive transfusion is an independent risk factor for developing multi-organ failure.\(^{146}\)

**Complications\(^{147}\)**
- The complications described below are dependent on the following factors:
  - Number of units transfused
  - Rapidity of transfusion
  - Patient factors

1. **Dilutional coagulopathy**
   - 50% of massively-transfused patients develop an INR >2.0 and about 33% have thrombocytopenia with a platelet count <50 x 10\(^9\)/L.\(^{148}\)
   - Number of RBCs transfused does not accurately predict the need for platelet and FP transfusion; frequent laboratory measurements are required to guide transfusion decisions.
   - In one large randomized controlled trial, resuscitation of trauma patients with 1:1:1 was not found to be superior to resuscitation with a ratio of 2:1:1 (RBC:FP:PLT).\(^{149}\)
     - Only patients with extremely rapid hemorrhage were enrolled in this trial and formula-driven resuscitation should not be applied to less extreme hemorrhage situations.\(^{149}\)

2. **Hypothermia**
   - Rapid infusion of cold blood can result in cardiac arrhythmias.
   - Prevention is critical – if massive transfusion is likely, use an approved and properly maintained blood warmer.

---

**Pediatric definitions\(^{150,151}\)**
- Transfusion support to replace ongoing blood loss of >10% TBV per min
- Transfusion >100% TBV in 24 hours
- Transfusion >50% TBV in 3 hours

---

**ATTENTION**

Use laboratory monitoring where possible to guide the use of blood components.

**ATTENTION**

RBCs currently contain 20 mL of plasma or less. Trauma patients can safely be transfused their native blood group if they have received 20 or less units of group O uncrossmatched RBCs (approximately 400 mL of group O plasma or less).
Mortality after massive transfusion is inversely related to core temperature (data from 1987): $^{152}$
- $<34{\degree}C$ – 40%
- $<33{\degree}C$ – 69%
- $<32{\degree}C$ – 100%

Every 1 °C drop in temperature increases blood loss by 16% and the risk of transfusion by 22%. $^{153}$

Risk of clinically important hypothermia is significantly increased by infusion of 5 or more units of blood. $^{152}$

Consequences of hypothermia:
- Platelet dysfunction
- Decreased coagulation factor activity
- Reduced clearance of citrate
- Decreased cardiac output
- Hypotension
- Arrhythmias (especially if cold blood is transfused rapidly through a central line)

### 3. Hypocalcemia/Hypomagnesemia/ Citrate toxicity

- Citrate is the anticoagulant used in blood components.
- It is usually rapidly metabolized by the liver.
  - A normothermic adult not in shock can tolerate upwards of 20 units per hour without calcium supplementation
- With massive transfusion, the capacity of the liver to degrade citrate may be overwhelmed.
- Citrate binds ionic calcium and magnesium, causing functional hypocalcemia, hypomagnesemia, and also metabolic alkalosis (from bicarbonate, a metabolite of citrate).
Clinical symptoms include: hypotension, narrow pulse pressure, elevated pulmonary artery pressure, tetany, paresthesia and arrhythmias.

If hypocalcemia develops OR patient develops signs or symptoms of hypocalcemia then administer:

- 1 gram (1 ampoule) of calcium chloride IV at maximum rate of 100 mg/minute

4. Metabolic acidosis

- Rare; from acid pH of blood products.
- Usually, metabolic alkalosis occurs due to bicarbonate production from citrate metabolism.
- May be an indicator of lactic acidosis in patients with tissue hypoperfusion.

5. Hyperkalemia

- Release of potassium from stored RBCs increases with storage time and after irradiation.
- Potassium concentration in a non-irradiated SAGM-RBC unit is approximated by the number of days of storage (110 mL of supernatant/unit).
  - For example, a 42 day old RBC has a potassium concentration of approximately 45 mmol/L.
- Order bloodwork q1h (e.g., CBC, INR, PTT, fibrinogen, calcium, arterial blood gas, potassium).
KEY COMPONENTS OF A HOSPITAL MASSIVE HEMORRHAGE PROTOCOL

Every hospital must have a Massive Hemorrhage Protocol to ensure standardized care is delivered.156

- Prompt use of measures to prevent hypothermia, including use of a blood warmer for all IV fluids and blood components.
- Monitor core temperature and maintain above 36 °C.
- Watch for dilutional coagulopathy with q1h blood work.
  - While patient is actively bleeding, transfuse to keep:
    - Platelet count >50 x 10⁹/L (with head injury >100 x 10⁹/L)
    - INR <1.8
    - Fibrinogen >2.0 g/L
  - Institute ratio-based resuscitation if the required rate of transfusion exceeds 4 units of RBC per hour
  - Administer tranexamic acid 1 gram IV bolus and then 1 gram IV over 8 hours157
- Watch for hypocalcemia, acidosis and hyperkalemia.
- Blood tubing must be changed every 2-4 units and within the number of hours specified by your hospital policy. In massive transfusion this may be impractical so an add-on filter can be used to minimize the frequency of tubing changes. Rapid infusers with large blood filters may allow for less frequent tubing changes.
Postpartum Hemorrhage (PPH)

- The above Massive Hemorrhage Protocol also applies to the patient with a massive postpartum hemorrhage.
- All postpartum females should be closely monitored for early signs of hemorrhage.
- Protocols for rapid administration of uterotonics must be in place at all hospitals with obstetrical patients.
- Use of intrauterine balloons should be a key part of the early management while a decision is being made regarding definitive therapy (i.e., hysterectomy vs. uterine artery embolization).
- RBC transfusion, when indicated clinically, should NOT be delayed while waiting for pre-transfusion testing and uncrossmatched blood should be administered.
  - uncrossmatched blood must be available within 10 minutes of the onset of a postpartum hemorrhage at all hospitals with obstetrics.
- Maintain fibrinogen level above 2.0 g/L with early and aggressive use of cryoprecipitate.158
Blood Conservation in the Perioperative Setting

Patient Blood Management Programs are the vehicle for delivery of blood conservation measures, and may be defined as integration of multi-modal, multi-disciplinary measures to reduce the risk of unnecessary transfusion and optimize patient outcomes.\textsuperscript{159,160}

- There are currently several perioperative blood conservation strategies available to patients.
- Patients that are at high risk of perioperative transfusions (>10% chance of allogeneic RBC transfusion) must be identified as early as possible, preferably at least 28 days before surgery, and must be offered appropriate blood conservation strategies.
  - As transfusion risk varies from institution to institution and surgeon to surgeon for the same procedure, each institution must determine its own requirements for transfusion.

Likelihood of Transfusion

- The risk of transfusion is increased by the following factors: lower hemoglobin, older age, lower weight, female gender, type of surgery, urgency of surgery, and renal dysfunction.
- Shown here is the probability of transfusion for patients undergoing cardiac surgery based on pre-operative hemoglobin.\textsuperscript{161}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{probability_transfusion.png}
\caption{Probability of transfusion based on preoperative hemoglobin.}
\end{figure}
**Blood Conservation Strategies**
The following blood conservation strategies are available, listed according to when they should be implemented perioperatively:

<table>

</tr>
</tbody>
</table>
GOOD SURGICAL TECHNIQUE

- Using good surgical technique(s) is critically important in reducing a patient’s exposure to allogeneic blood.

Recommended surgical practices

- The following good clinical practices are highly recommended:
  - Assess and treat nutritional status preoperatively
  - Maintain normothermia intraoperatively
  - Careful ligation of blood vessels
  - Avoid tissue trauma
  - Optimal use of electrocautery
  - Meticulous attention to surgical hemostasis
  - Utilize avascular tissue planes
  - Appropriate use of topical hemostatic agents

Consider stopping anti-platelet and anticoagulants before major surgery

- Acetylsalicylic acid (Aspirin®), clopidogrel (Plavix®) and prasugrel (Effient®): 162,163
  - In most clinical situations, withholding ASA before non-cardiac surgery is not associated with an increase in adverse cardiac events164
  - Primary prevention: 48 hours minimum, 7 days preferable
  - Secondary prevention (after remote MI, stroke, peripheral artery disease)
    - low risk of bleeding procedure (e.g., cataract surgery, plastic surgery): no need to stop antiplatelet agents
    - high risk of bleeding procedure (e.g., neurosurgical procedure): 48 hours minimum, 7 days preferable
  - Secondary prevention (high risk for arterial thrombosis – recent percutaneous coronary intervention, MI, stroke OR coronary stent <12 months)
    - consult patient’s cardiologist or neurologist for expert advice
    - only stop antiplatelet agents if risk of bleeding exceeds risk of cardiovascular complications

ATTENTION

Do not stop antiplatelet agents without consultation with the patient’s cardiologist or neurologist, if:
- recent thrombosis (MI, stroke)
- recent percutaneous coronary intervention (PCI)
- coronary stent in last 12 months
- **Dabigatran (Pradaxa®):**
  - Consider stopping therapy 2-4 days before major surgery in patients with normal renal function
  - In patients with renal dysfunction (creatinine clearance <50 mL/min) consider stopping 4-5 days before major surgery

- **Rivaroxaban (Xarelto®) and Apixiban (Eliquis®):**
  - Consider stopping therapy 2-3 days before major surgery in patients with normal renal function
  - In patients with renal dysfunction (creatinine clearance <50 mL/min) consider stopping 3-4 days before major surgery

- **NSAIDs:**
  - Consider stopping therapy 4-7 days before major surgery
  - Celecoxib does not inhibit platelet aggregation at usual doses

**Minimize blood sampling and loss**

- Restrict diagnostic phlebotomy.
- Use small volume tubes and testing methods.
- Conduct bedside microanalysis.
- Remove arterial and venous catheters when no longer necessary.

**Preoperative patients on Warfarin:**

- If low risk of thromboembolic events (e.g., primary prophylaxis of atrial fibrillation):
  - Stop warfarin 4-5 days preoperatively; repeat INR 1 day preoperatively
  - If INR >1.5 then give 2 mg oral vitamin K
  - Then repeat INR preoperatively

- If high risk of thromboembolic events (e.g., recent deep vein thrombosis):
  - Consider switch to unfractionated or low molecular weight heparin 4 days preoperatively; consult with hematology on timing and preferred regimen or consult recommendations at http://thrombosiscanada.ca/

**Emergency reversal of anticoagulants**

- See page 126.
IRON

- All patients undergoing procedures with significant blood loss should be evaluated for iron deficiency and where present corrected preoperatively.\textsuperscript{160}
- There are several randomized trials of iron therapy administered perioperatively, finding that:
  - Preoperative iron may be helpful for patients with low preoperative hemoglobin levels, but not confirmed beneficial in all studies\textsuperscript{167,168,169,170}
  - Randomized trials failed to confirm a benefit of post-operative iron therapy in patients that were not anemic preoperatively\textsuperscript{171,172,173,174,175,176}

Dosage

- 60 mg of elemental iron/day is sufficient for the majority of patients. (Higher doses do not appear to improve the response, higher doses decreases compliance, and higher doses causes decreased absorption by increasing the hormone hepcidin.)\textsuperscript{177}

<table>
<thead>

</table>
Common Adverse Events*

- GI upset (diarrhea, nausea, constipation) was twice as frequent with oral iron as with placebo.\textsuperscript{178}
- Dark stools.
- Patient compliance with oral treatment is about 50%.\textsuperscript{179}

* See product monograph for details

**INTRAVENOUS IRON**

- There is currently insufficient evidence to support the routine use of intravenous iron in elective surgery patients.\textsuperscript{180}
- Patients with iron deficiency anemia (whose surgery should not be delayed to allow for oral iron therapy to correct the anemia) may be treated with intravenous iron, in addition to oral iron.\textsuperscript{181} IV iron tends to restore iron stores and hemoglobin levels more rapidly than oral iron.\textsuperscript{179,182,183}

**Dosage**

- Check your hospital’s formulary to determine the recommended type of parenteral iron

**Adverse reaction**

- 24/100,000 risk of anaphylactic reaction to iron dextran\textsuperscript{184}
- 16/100,000 risk of anaphylactic reaction to iron sucrose Venofer\textsuperscript{®}\textsuperscript{184}
- Give sufficient iron to correct the anemia (e.g., 300–1,000 mg of elemental iron, Venofer\textsuperscript{®} 300 mg in 250 mL of normal saline over 2 hours for 1-3 infusions.)

**Pediatric**

FeraMAX (15 mg elemental iron per ¼ teaspoon)\textsuperscript{185}

- May be dissolved in water or mixed into soft foods or powdered cereals:
  - Age based dosing:
    - Less than 2 months: ¼ teaspoon daily
    - More than 2 months to 13 yrs: ¼ to ½ teaspoon daily
    - More than 13 yrs to 18 yrs: ¼ to ¾ teaspoon daily
INTRAOPERATIVE CELL SALVAGE

Principles
- A patient’s own blood shed at the time of an operation is collected and processed in such a way that it can be re-infused into the patient (auto-transfusion).
- Up to 80% of red cells can be recovered.\textsuperscript{186}

Indication
- Meta-analysis of 75 studies:\textsuperscript{187}
  - Cell salvage in orthopedic surgery (all types of salvage devices, washed and unwashed)
    - Relative risk of transfusion 0.46 (95% CI 0.37-0.57)
  - Cell salvage in cardiac surgery (unwashed only)
    - Relative risk of transfusion 0.77 (95% CI 0.69-0.86)
  - No increase in adverse events in the treatment group
- Meta-analysis of 31 randomized controlled trials, including 2282 patients, in the setting of cardiac surgery found that cell salvage decreased the risk of allogeneic blood exposure (OR 0.63, 95% CI 0.43-0.94, \(P=0.02\)).\textsuperscript{188}
- Consider in the setting of: trauma, hepatic resection, major orthopedic and spine surgery, or ruptured aneurysm with appropriate quality assurance.
- May be an acceptable alternative for some Jehovah’s Witnesses (see Appendix B, page 145).
Complications

- Complications include:
  - Air embolism – ensure air is removed prior to re-infusion
  - Thrombocytopenia and dilutional coagulopathy
  - Bacterial contamination (rare)
  - Tumour dissemination in cancer surgery
  - Hemolysis – ensure correct wash fluids are used

- A formal maintenance program is required for equipment

Contraindications

- Malignant cells in operative field (risk may be mitigated by leukoreduction filter).
- Bacterially-contaminated operative fluid, ascitic fluid, or amniotic fluid in operative field.
- Use of hypotonic solutions in the operative field.
- Use of topical thrombogenic agents in the operative field.

**ATTENTION**

Air embolism is a risk of intraoperative cell salvage.
ERYTHROPOIETIN IN ELECTIVE SURGERY

Principles

- Erythropoietin stimulates erythropoiesis and is produced in response to hypoxia by the renal cortex. Regulation is by classical negative feedback inhibition.
- Erythropoietin is administered prior to elective surgery to increase hemoglobin and thereby reduce the rate of allogeneic transfusion.\(^{189}\)
  - Expected rise in hemoglobin is 10-20 g/L

Eligibility and Dosage

- Patients with a hemoglobin < 130 g/L and a probability of requiring a blood transfusion of 10% or greater.\(^{189,190,191}\)
- Preferred dose: 600 U/kg sc qwk for up to 4 doses commencing 28 days before surgery.\(^{192,193,194}\)
  - e.g., 30,000 or 40,000 U sc qwk x 4 weeks, start 28 days pre-op
- Alternative dose: 300 U/kg sc qd x 15 days commencing 10 days preoperative.\(^{195}\)
  - e.g., 20,000 U sc qd x 15 days, start day 10 pre-op
- Supplemental iron advised.\(^{196}\)
**Contraindications** (in elective surgery patients)

- Uncontrolled hypertension.
- Hypersensitivity to mammalian-derived cell products, albumin, or other components of the product.
- Contraindicated in patients scheduled for elective surgery with severe arterioscerotic disease.

For more details, refer to product monograph.

**Adverse Effects**

- Safety of short-term use before surgery has not been thoroughly studied.
- A recent study found an increased risk of thrombosis in patients undergoing elective spine surgery.\textsuperscript{197}

For more details, refer to product monograph.
ANTIFIBRINOLYTICS

General Principles\textsuperscript{198,199}

- Inhibitors of plasminogen activation are administered to prevent/treat increased fibrinolysis during surgery, particularly cardiac surgery.

Indications

1. Antifibrinolytics in Cardiac Surgery\textsuperscript{198,200}

- Prophylactic administration is preferred rather than at time of marked hemorrhage.
- Tranexamic acid reduces bleeding and transfusion rates.

2. Tranexamic Acid in Non-Cardiac Surgery\textsuperscript{157,201,202,203}

- Used in orthopedic surgery, trauma, and hepatic surgery.
- Evidence suggests a high degree of safety:
  - A major meta-analysis included 252 RCTs including over 25,000 participants
  - In the tranexamic acid trials, there was a significant reduction in allogeneic transfusion (RR 0.61, 95\% CI 0.53-0.70)
The CRASH-2 study, which included over 20,000 patients (most from developing countries), provides strong evidence of benefit for tranexamic acid in patients with traumatic hemorrhage (dose used: 1 g loading over 10 minutes, then infusion of 1 g over 8 hours).\textsuperscript{157}

The use of topical tranexamic acid in knee and hip joint replacement is equally effective as intravenous use.\textsuperscript{204}

**Adverse Effects**

- Tranexamic acid: GI upset, seizures.
  - Data from meta-analyses do not suggest an increased risk of thrombosis\textsuperscript{199}

**Contraindications\textsuperscript{205}**

- Tranexamic acid – patients at elevated risk of thrombosis, pregnancy; dose adjustment required in renal failure.

Refer to product monograph for more details.
**DDAVP**

- There is no convincing evidence that DDAVP minimizes perioperative allogeneic RBC transfusion in patients who do not have congenital bleeding disorders and its routine use is not recommended.\(^{206,207,208}\)
- DDAVP is of no benefit in the management of bleeding post cardiac surgery.\(^{209}\)

**ATTENTION**

DDAVP is not indicated as a routine practice in the prevention or treatment of bleeding after cardiac surgery.

**REGIONAL ANESTHESIA**

- One systematic review of literature found that the use of **neuroaxial blockage with epidural or spinal anesthesia** reduced the risk of:\(^{210}\)
  - transfusion
    - risk of transfusion was reduced by 50%
  - venous thromboembolism
  - pneumonia and respiratory depression

**TOPICAL AGENTS\(^{200,211}\)**

- Fibrin sealants:
  - Mixture of fibrinogen, thrombin, calcium chloride and anti-fibrinolytic agent
  - Meta-analysis of 18 trials indicates effectiveness in reducing peri-operative allogeneic blood transfusion (RR 0.63, 95% CI 0.45-0.88)\(^{212}\)
- Topical thrombin:
  - Bovine thrombin products are not recommended for clinical use\(^{200}\)
  - Recombinant human thrombin available (e.g., Recothrom®)\(^{213}\)
  - No data on effectiveness in reducing peri-operative allogeneic blood transfusion
OTHER BLOOD CONSERVATION STRATEGIES
UNDER CLINICAL INVESTIGATION

The following blood conservation strategies are obsolete, under investigation or highly limited in application:

- Pre-operative autologous blood donation.
- Hemoglobin-based oxygen carriers.\textsuperscript{214}
- Recombinant factor Vlla.\textsuperscript{215}
- Hypervolemic hemodilution.
- Acute normovolemic hemodilution.
General Principles\textsuperscript{216,217}

- Erythropoietin (EPO) is synthesized by DNA technology:
  - Currently available formulations in Canada do not contain albumin
- Requires readily available iron for full efficacy.
- Takes time to increase hemoglobin (weeks).
- EPO response to anemia may be blunted in the presence of malignancy, chemotherapy and chronic inflammatory diseases.

Indications

- Chronic renal failure.
- Anemia associated with malignancy.

Contraindications\textsuperscript{218}

1. Uncontrolled hypertension.
2. Known sensitivity to mammalian cell derived products.
3. Hypersensitivity to the active substance or to any of the excipients.
4. Patients scheduled for elective surgery, who are not participating in an autologous blood pre-deposit program and who have severe coronary, peripheral arterial, carotid or cerebral vascular disease, including patients with recent myocardial infarction or cerebral vascular accident.
5. Surgery patients who for any reason cannot receive adequate antithrombotic prophylaxis or treatment.
6. Patients who develop Pure Red Cell Aplasia (PRCA) following treatment with any erythropoietin should not receive EPREX or any other erythropoietin (see PRCA paragraph in Precautions in monograph).

Refer to product monograph for more details.
**CHRONIC RENAL FAILURE (CRF)**

*Rationale*
- Patients with end-stage renal disease are unable to produce erythropoietin; it is administered as a replacement therapy.
- Erythropoietin decreases the likelihood of transfusion (RR 0.32, 95% CI 0.12-0.83).

*Eligibility*
- Patients with clinically and biochemically established CRF with a hemoglobin <90-110 g/L should be considered.
- Usually erythropoietin is considered when the creatinine clearance is <60 mL/min/1.73 m².
- Other causes of anemia must be excluded or successfully treated:
  - Initial laboratory work up should include a CBC, reticulocyte count, serum ferritin, and transferrin saturation

*Target therapeutic outcome*
- To maintain the hemoglobin in the range of 100 to 120 g/L.

*Iron*
- Assess iron status every 3 months.
- Sufficient iron should be administered to maintain the serum ferritin >100 ug/L (not on hemodialysis) or >200 ug/L (on hemodialysis) AND iron saturation >20%.
- Intravenous iron is frequently utilized for patients who fail oral iron.
- Intravenous or oral iron is acceptable for CRF patients not on hemodialysis.
- Patients should be monitored to prevent iron overload.
- Stop iron if ferritin >500 ug/L.

Refer to intravenous iron product monographs for more details.

*Dosage*
- **Correction Phase:**
  - Initial dose of Epoietin Alfa (EPREX) - 50 IU/kg of body weight three times a week intravenously or subcutaneously or darbopoietin (Aranesp™) 0.45 ug/kg sc per week
If the hemoglobin does not increase by 10 g/L after one month of treatment, the dosage may be raised to 75 IU/kg three times per week (EPREX) or by 25% (Aranesp™)

- If further increments are needed they should be at 25 IU/kg, three times per week, at monthly intervals, to achieve a hemoglobin NOT to exceed 120 g/L
- The maximum dosage should not exceed 200 IU/kg three times per week

**Maintenance Phase:**
- The intravenous/subcutaneous dose adjusted individually to maintain a hemoglobin not to exceed 120 g/L
- The maintenance dose should be individualized for each patient with chronic renal failure
- The recommended weekly dose is between 75 and 300 IU/kg
- In patients who are converting from the subcutaneous to intravenous route, the same dose should be used
- Follow hemoglobin closely (e.g., weekly) so that appropriate changes in the dose can be made to keep the hemoglobin in the target range

**Dose Adjustment:**
- If the hemoglobin is increasing and approaching 120 g/L, the dose should be reduced by approximately 25%
- If the hemoglobin continues to increase, withhold treatment until the hemoglobin begins to decrease, then resume therapy at a dose approximately 25% below the previous dose
- If the hemoglobin increases by more than 10 g/L in any two week period, decrease the dose by by approximately 25%
- Dose reduction may be achieved either by reducing the amount per dose or the number of doses per week, or both

Where inadequate responses occur, re-examine for other causes of anemia.
ANEMIA ASSOCIATED WITH MALIGNANCY

Eligibility

- Patients with chemotherapy-induced anemia; AND
- Hemoglobin <100 g/L and/or requiring red cell transfusions.
  - Other contributing causes of anemia must be excluded or successfully treated
  - Carefully weigh the risks of thromboembolism in patients prescribed erythropoietin
    - The relative risk of thromboembolic complications is increased (RR 1.52, 95% CI 1.34-1.74).\(^{230}\)
  - Erythropoietin should not be used in treatment of anemia associated with malignancy in patients not receiving chemotherapy
    - A meta-analysis of 91 studies including 20,102 patients suggested erythropoietin therapy increases the risk of death compared to placebo (Hazards Ratio 1.05, 95% CI 1.00-1.11)\(^{230}\)
    - Red blood cell transfusion should be considered the preferred strategy in patients undergoing potentially curative treatment

Target outcome

- To maintain the lowest hemoglobin level sufficient to avoid RBC transfusions.
- Erythropoietin increases the hemoglobin level and decreases the likelihood of transfusion (RR 0.65, 95% CI 0.62-0.68).\(^{230}\)

Dosage

- Iron status should be assessed and iron deficiency treated.
- Concurrent iron therapy recommended unless there are concerns of iron overload.
- Start erythropoietin with a dose of either:
  - EPREX 150 U/kg sc 3 times/week or 40,000 U sc weekly; or Darbepoetin 2.25 ug/kg sc weekly or 500 ug every 3 weeks sc
- Adjust dose per product monograph to avoid major fluctuations in hemoglobin level.
Basics

- Albumin is a plasma protein synthesized by the liver and catabolized by the endothelium (daily turnover 9-12 g; average total body albumin of a 70 kg patient is 280 g; ~60% interstitial).\textsuperscript{231}
- Manufactured by cold ethanol fractionation from a pool of approximately 10,000 blood donors.
- Viral inactivation steps include cold ethanol fractionation, and heat inactivation.
- In 2014-2015, 8 million grams of albumin were used in Canada, at a cost of about $15 million dollars.
**Administration & Infusion Practices**

**Dosage**
- **Caution:** Administering 25% albumin in error, instead of 5%, could result in severe circulatory overload.
- For dosage, see specific indications listed below.
- Intravascular volume response:

  - **500 mL** 5% albumin
    - = 25 grams of albumin
    - **500 mL** increase in intravascular volume
  - **100 mL** 25% albumin*
    - = 25 grams of albumin
    - **450 mL** increase in intravascular volume (350 mL from interstitial pool)

  *25% albumin usually restricted to use in patients with liver failure

**Administration**\(^{232,233}\)
- No crossmatch is required.
- Use regular IV tubing.
- Fluid compatibility: all IV solutions.
- Record lot number and volume of albumin administered in patient chart.

**Adverse reactions / Risks**
- Anaphylaxis – rare.
- Circulatory overload.
- Hypotension – rare case reports of transient hypotension in patients on angiotensin-converting enzyme inhibitors.\(^{234}\)
- There are no reports of HIV, HCV, or other viruses transmitted through albumin.
**Indications**

ALBUMIN MAY BENEFIT THE FOLLOWING GROUPS OF PATIENTS:

1. **Paracentesis**
   - Albumin has been shown to reduce morbidity and mortality in the management of tense ascites by paracentesis.\(^{235}\)
   - For paracentesis of <5 litres – albumin is unnecessary.\(^{236}\)
   - For large volume paracentesis, albumin should be considered as the replacement fluid of choice.

<table>
<thead>
<tr>
<th>VOLUME OF ASCITES</th>

<tr>
<td>8-12 L</td>
<td>3</td>
</tr>
<tr>
<td>12-15 L</td>
<td>4-5</td>
</tr>
</tbody>
</table>

* 8 grams albumin per L of fluid removed for paracentesis >5 L.\(^{237}\)

- There is preliminary evidence that midodrine\(^{238}\) and terlipressin\(^{239}\) may be alternative therapies to intravenous albumin in this setting, but have not been shown to be superior to albumin.\(^{240}\)
- **Malignant ascites** – there is no evidence to support the use of albumin in patients with malignant ascites post-paracentesis.\(^{241}\)

2. **Spontaneous bacterial peritonitis**
   - One RCT (n=126) found that patients resuscitated with antibiotics alone compared to antibiotics plus albumin had a higher mortality (OR 4.5, 95% CI 1.0 to 20.9).\(^{242}\)
   - This study has been criticized for lack of a formalized resuscitation protocol in the control arm

**ATTENTION**

There is no evidence to support the use of albumin in patients with malignant ascites post-paracentesis.
Erythropoietin and Medical Patients Sickle Cell Disease

3. Hepatorenal syndrome
- Preliminary data suggests that albumin in conjunction with terlipressin or midodrine/octreotide may be effective in salvaging some patients with type 1 hepatorenal syndrome who are candidates for liver transplantation. There is evidence that the combination of terlipressin and albumin has a greater beneficial effect on renal failure than the combination of either midodrine or octreotide with albumin.
  - This therapy has not been shown to change mortality rates in hepatorenal syndrome.
  - Albumin alone, without terlipressin or other agent is ineffective.

DOSAGE
- 100-200 mL of 25% albumin daily with above agents, up to a maximum of 14 days.

4. Plasma exchange
- Currently, the majority of patients undergoing therapeutic plasma exchange are replaced with albumin ± crystalloid or starch, with the exception of patients with thrombotic thrombocytopenic purpura (TTP) who are replaced with cryosupernatant or frozen plasma.
THE CURRENT MEDICAL LITERATURE CANNOT CONFIRM ANY BENEFIT OF INTRAVENOUS ALBUMIN IN THE FOLLOWING SUBGROUPS OF PATIENTS: 248

1. Resuscitation
   - Current evidence: albumin is not superior to crystalloid for resuscitation in intensive care.
   - A large randomized controlled trial 249 showed no overall advantage of albumin over crystalloid for resuscitation in intensive care patients.
   - A large randomized trial in critically ill patients with hypovolemic shock (half with septic shock) found no difference in 28 day mortality when albumin was compared to crystalloid. 250

2. Hypoalbuminemia
   - Current evidence: albumin is NOT superior to crystalloid for treatment of hypoalbuminemia.
   - One meta-analysis showed a significant increase in mortality and another showed a non-significant increase in mortality compared to crystalloid:

<table>
<thead>
<tr>
<th>Odds Ratio (OR)*</th>
<th>OR Range</th>
<th>% Increase in Mortality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cochrane Injuries Group 248</td>
<td>1.69</td>
<td>1.07-2.67</td>
</tr>
<tr>
<td>Wilkes et al 251</td>
<td>1.59</td>
<td>0.91-2.78</td>
</tr>
</tbody>
</table>

3. Severe burns
   - 4 small randomized controlled trials with important methodological limitations in patients with thermal injuries failed to show that 5% albumin was superior to crystalloids. 248, 252
   - There is currently a wide variation in fluid resuscitation practice in burn patients. 253
Current expert opinion recommends resuscitation with lactated Ringer’s solution according to the Parkland formula, with addition of colloids if the fluid volume exceeds 4 mL/kg/% burn (known as ‘fluid creep’) and urine output is less than 0.5 mL/kg/hour, with hemostatic instability after the first 8-24 hours.\(^{254,255}\)

- Intravenous albumin should only be commenced after transfer to a specialized burn centre.

4. Hypotension during dialysis
- There are currently no data to support the use of albumin in the treatment of hypotension during dialysis.
  - Small comparison trials of normal saline, albumin (20%), and starch did not suggest a superiority of albumin over the other agents\(^{256}\)
  - A small RCT concluded that 5% albumin was no more effective than normal saline for the treatment of hypotension during dialysis\(^{257}\)

5. Cardiac surgery\(^{258}\)
- There is no evidence to support the use of albumin, as compared to starch or crystalloid, for either:
  - Priming fluid for cardiopulmonary bypass
  - Post-cardiopulmonary bypass
- There is no evidence from randomized clinical trials in cardiac surgery patients that fluid replacement with albumin is associated with a better pulmonary, cardiac, or renal outcome.

6. Acute Lung Injury
- Two small, industry funded randomized control trials (n=40\(^{259}\), n=37\(^{260}\)) in hemodynamically stable patients found the combination of furosemide and intravenous albumin to result in weight loss of 10 kg over 5 days, without improvement in the rate of extubation success or mortality.
IVIG is the fraction extracted from donated plasma that contains the immunoglobulins, with >90% as IgG.

Products Available
- Products are supplied by CBS or HQ.
- Informed consent is required as for any blood component or product.

Refer to product’s package insert for further details.

Cost

- IVIG costs $54 per gram, depending on US$ exchange rate.
  - A single course of treatment for a 70 kg patient with the commonly prescribed dose of 1 g/kg each day for 2 days, costs $7,500

Availability & Consumption

- Approximately 20% of the IVIG used in Canada is derived from Canadian plasma.\textsuperscript{263}
- The rest is derived from paid U.S. donors.
- Canada has the highest per capita consumption of IVIG in the world.\textsuperscript{264}

<table>
<thead>
<tr>

</tbody>
</table>

Manufacturing

- IVIG is manufactured from pooled plasma obtained from several thousand donors per pool.
- The constituent plasma units are tested for human immunodeficiency virus (1 and 2), hepatitis B, hepatitis C, human T-cell lymphotropic virus (I and II), and parvovirus B19.
- The process includes rigorous viral inactivation steps (e.g., caprylate, low pH, chromatography, solvent detergent treatment).
- There is no evidence of transmission of prion disease (e.g., variant CJD) through IVIG.
- Steps in manufacturing are believed to reduce the risk of transmission of prion disease.\textsuperscript{265}

IN 2015-2016

Canada (minus Quebec) used 4,780 kg of IVIG at a cost of $235 million dollars.\textsuperscript{263}

IN ONTARIO

In Ontario, requests for IVIG for infusion are required to be made on a MOHLTC – mandated request form. The IVIG request form can be found at www.transfusionontario.org.
Administration & Infusion Recommendations

Administration
- For detailed recommendations for infusion of IVIG, refer to “Intravenous Immune Globulin Toolkit for Ontario”.266
- Administered as 5% or 10% solution usually dispensed by the Transfusion Medicine Laboratory or Pharmacy.
- Safe for use in pregnancy.
  Refer to package insert for further details.

General Principles
- Refer to Institution specific policies
- Use Adjusted Body Weight Dosing Calculator267, check every 6 months or if significant weight change.
- Round dose to nearest vial size.

Pre-infusion
- Verify documentation of order, clinical indication and consent.
- Identify patients at risk for complications, especially TACO (see page 60) and thromboembolic events.
- Check vital signs.

Infusion
- Slow initial rate for first 30 minutes.
- Check vital signs.
- Increase rate and monitor vital signs as per institutional policy.
- Monitor for signs of adverse reactions and report according to institutional policy.

Post-infusion
- Complete documentation including dose, brand and lot number.
- Report and return to the TML or Pharmacy any unused or defective vials, and any vials associated with an adverse event.

</tr>
</tbody>
</table>

** Reactions are more likely with faster rates of infusion.
Indications

**Immunology**
- There is good evidence to support the use of IVIG in congenital and acquired immunoglobulin deficiency, with the following conditions:
  - Significant quantitative or functional antibody deficiency that has been established (see the “Choose Wisely” statement)
  - Clinical evidence consistent with defective humoral immunity (e.g., recurrent infection)
  - The full text describing a scoring system to aid clinical decision making regarding immunoglobulin therapy is available at ncbi.nlm.nih.gov/pubmed/23518142277
  - Treatable conditions to which antibody deficiency may be secondary must be excluded
- Subcutaneous immunoglobulin also available for home-based immunoglobulin replacement therapy. Consult a transfusion medicine specialist or immunologist for additional information.

**IVIG IN IMMUNOGLOBULIN DEFICIENCY**278,279

<table>
<thead>
<tr>
<th><strong>Diagnosis</strong></th>
<th><strong>Efficacy/Comment</strong></th>
<th><strong>Dose</strong></th>
</tr>
</thead>
</table>
| Primary Immune Deficiency280 | IVIG is recommended in hypogamma-globulinemia (total IgG or IgG subclasses reduced) with recurrent bacterial infections | Adult: 0.4-0.6 g/kg/ every 4 weeks  
Pediatric: 0.3-0.6 g/kg/ every 4 weeks  
Monitor IgG trough level to maintain low range |
| Secondary Immune Deficiency (SID) | | |
| Hematopoietic Stem Cell Transplant in primary immunodeficiencies281 | IVIG is recommended in PID patients undergoing stem cell transplant | 0.4-0.6 g/kg/every 4 weeks; requirements may increase and should be based on clinical outcome |

**Choose Wisely**

Immunoglobulin (gammaglobulin) replacement does not improve outcomes unless there is impairment of antigen-specific IgG antibody responses to vaccine immunizations or natural infections. Isolated decreases in immunoglobulins (isotypes or subclasses), alone, do not indicate a need for immunoglobulin replacement therapy. Exceptions include genetically defined/suspected disorders. Measurement of IgG subclasses is not routinely useful in determining the need for immunoglobulin therapy. Selective IgA deficiency is not an indication for administration of immunoglobulin.

- Bone marrow transplant and red cell aplasia due to parvovirus B19: see Hematology.
- Specific hyper-immune globulins are available from Canadian Blood services for the listed conditions:
  - Varicella-Zoster Immune Globulin (VZIG)
  - Hepatitis B Immune Globulin (HBIG;BayHepB)
  - Anti-RSV Immune Globulin (Respigam®)
  - Cytomegalovirus Immune Globulin (CMVIG, Cytogam®) 324
Dosing of IVIG for Obese Patients

The dose of IVIG varies depending on the clinical condition. In general, the dose is based on the patient’s weight. In the case of obese patients, the appropriate dosing regimen is unclear. It is suggested that patients weighing more than 100 kg and with a body mass index greater than 30 kg/m² should have their IVIG dose calculated using an adjusted body weight. The adjusted weight takes into account the increased volume of distribution in these patients (because of increased body fluids) without accounting for the increase in weight from body fat.

A tool which assists with the calculation of the appropriate dose of IVIG based on the patient’s gender, height and weight is available at http://ivig.transfusionontario.org/bmi/.

Requests for IVIG for infusion in Ontario

Requests for IVIG for infusion are required to be submitted on the Request Form prescribed by the MOHLTC. The form and the protocol for its use are posted at www.transfusionontario.org.

ATTENTION

IVIG in Ontario can only be requested using the prescribed request form.

Prothrombin complex concentrates (PCCs) are coagulation factor concentrates that contain factors II, VII, IX, X. The amount of the individual coagulation factor levels varies with the specific preparations.

**Manufacturing**
- The factor concentrate is made from pools of 1,000-2,000 plasma donations.
- Plasma units are tested for HIV (1 and 2), hepatitis B, hepatitis C.
- Manufacturing processes include viral inactivation steps.

**Products available**
- PCCs are supplied by CBS and HQ.
- Two prothrombin complex concentrates are licensed in Canada: Octaplex® and Beriplex®.

Monitoring & Infusion Practices for Octaplex® and Beriplex®

How

- Lyophilized powder must be reconstituted for administration.
- Final volume is 20 mL per vial which contains 500 IU of factor IX.
- Can be prepared in syringe or minibag for intravenous infusion.
- Vitamin K 5-10 mg IV (not intramuscular or subcutaneously) should be administered immediately to avoid rebound anticoagulation.

Dose

- The National Advisory Committee on Blood and Blood Products (NAC) Recommendations on dosing are based on the INR as detailed in the table to the right.
- If the INR is unknown and major bleeding is present, 2,000 IU (80mL) should be administered.
- The published NAC Recommendations include a table of detailed dosages based on a combination of INR and body weight, as an alternative dosing strategy.
- The maximum dose should not exceed 3,000 IU.

When

- Infusion rate should not exceed 3 mL/min for Octaplex® and 8 mL/min for Beriplex®.

Storage

- Store between +2 to +25°C for Octaplex® and room temperature (up to 25°C) for Beriplex®.
- Freezing and light exposure may affect product quality.

<table>

<tr>
<td>&gt;5</td>
<td>3,000 IU</td>
</tr>
</tbody>
</table>

ATTENTION

Vitamin K should be given intravenously at same time as PCCs to avoid rebound anticoagulation.

Monitor patient

- Check patient’s vital signs prior to starting, 15 minutes after starting, at end of transfusion and if there are any transfusion reactions.
- Repeat INR immediately postinfusion to ensure adequate correction of INR.
- Effective half life of PCC is approximately 6 hours.

INDICATIONS FOR PCCs

- Emergency reversal of warfarin effect.
  - For patients with INR ≥1.5 AND
  - “Life or limb” threatening bleeding
  - Emergency surgery within 6 hours
  
  Give:
  - Vitamin K 10mg IV
  - PCC

  For dosages, see table on page 125.

- PCCs should NOT be administered if:
  - INR ≤1.5 as individual coagulation factors are not below the level needed to maintain hemostasis
  - Patients with coagulopathies not related to warfarin or Vitamin K deficiency as they are deficient in coagulation factors not contained in PCCs (with the exception of the off-label uses described)
  - Patients with known HIT (Beriplex® and Octaplex® both contain heparin)
  - Patient has received or will receive recombinant Factor VIIa

- Clinical situations where vitamin K alone will suffice are shown in the “Choosing Wisely” box to the right.¹⁰
- Its use should be limited to life-threatening hemorrhage and patients requiring emergency surgery.
OFF-LABEL USES OF PCCs

- Reversal of anti-Xa inhibitors (Rivaroxaban and Apixiban).
  - Currently specific reversal agents are in clinical trials and are not available outside of clinical trials.
  - PCCs at a dose of 2,000 IU (repeated in 1 hour if hemostasis is not achieved) is being used across Canada.
  - Data to support its use is limited to studies in animals and human volunteers.

- Reversal of anti-IIa inhibitors (Dabigatran).\(^{329}\)
  - A licensed antidote (Idarucizumab, Praxbind\(^{\circledR}\)) is available in Canada.
  - The dose of Idarucizumab is 5 g, administered in two 2.5 g bolus infusions each over 5 minutes, not more than 15 minutes apart.
Rh(D) Immune Globulin (WinRho®)\textsuperscript{324,330}

**Purpose**
- Prevention of immunization in Rh(D) negative patients exposed to Rh(D) positive red cells.

**Dosages Available**
- 120 ug (600 IU), 300 ug (1,500 IU), 600 ug (3,000 IU), 1,000 ug (5,000 IU), IV or IM.

**Prevention of Rh(D) immunization by Rh(D) positive fetal red cells in pregnancy in non-sensitized Rh(D) negative females:**
- Recommended doses:
  - Prophylactic dose at 28 weeks 300 ug IV or IM
  - Post-partum, newborn Rh(D) positive (including weak D), 300 ug IV or IM, within 72 hours of delivery (give as soon as possible if 72 hour deadline is missed)
    - Quantify feto-maternal hemorrhage; additional doses of RhIG required if fetomaternal hemorrhage present (dose should be calculated by using the College of American Pathologist’s on line calculator at www.cap.org)
  - Complications of pregnancy:
    - Pregnancy before 12 weeks, 120 ug IV/IM
    - Pregnancy 12-20 weeks, 300 ug IV/IM
    - Pregnancy after 20 weeks, 300 ug IV/IM
      - Plus Fetal Maternal Hemorrhage (FMH) testing to determine if additional doses required
Complications of pregnancy requiring Rh(D) immune globulin:
- Antepartum hemorrhage
- Amniocentesis, chorionic villus biopsy or cordocentesis
- External version, abdominal trauma
- In-utero therapeutic interventions
- Ectopic pregnancy, intrauterine death and stillbirth
- Abortion, threatened, actual or therapeutic

Immunization with other red cell antigens:
- Severe hemolytic disease of the fetus and newborn may involve many antigens other than Rh(D), including, but not restricted to, Rh C, c, E, K and k, Fya, Jka, Jkb and S
- Specific immune globulin prophylaxis is not available for specificities other than Rh(D)

Other indications for treatment/prophylaxis with Rh(D) immune globulin:
- After transfusion of platelet components from Rh(D) positive donors.
  - ONLY to Rh(D) negative patients of childbearing potential
  - The presence of “passive” anti-D complicates red cell compatibility testing and may delay transfusion without significant benefit
  - The risk of Rh(D) immunization by platelet components is about 1% \(^{331,332}\)

Note: RhIG contains IgA at a concentration of 40 ug/mL or less.
Principles of Transfusion in Sickle Cell Disease

Transfusion in patients with sickle cell disease presents particular challenges, both in the practicalities of providing optimally matched red cells and in determining when transfusion is likely to provide superior outcomes to other available therapeutic measures. It is therefore important that expert consulting assistance be sought for the individual case.

Patients with sickle cell disease:
- Have elevated blood viscosity which may be exacerbated by increases in hematocrit.
- Are more likely to experience complications from transfusion.

The indications for transfusion in patients with sickle cell disease differ significantly from other patients:

- **Treatment of severe anemia:** in the absence of heart failure, dyspnea, hypotension or marked fatigue, transfusion should be avoided unless the hemoglobin (Hgb) has decreased to <50 g/L. A rapid decrease in Hgb can be anticipated if the reticulocyte count falls below 250 x 10⁹/L.

- Aim to decrease the sickle cell hemoglobin (HgbS) concentration while keeping the total Hgb below 100 g/L in patients with sickle cell complications.

- Augmentation of oxygen delivery in patients with sickle cell disease is achieved more efficiently through decreasing the HgbS% than by increasing the total Hgb level.
Special Transfusion Requirements

- No special precautions are required for patients with HgbAS (sickle cell trait).
- Notify the hospital’s Blood Transfusion Service whenever a patient with sickle cell disease presents, to allow sufficient time to prepare specialized blood products should the need for transfusion arise.

Phenotypically-matched RBCs

- Determine extended phenotype (Rh, Kell, Duffy, Kidd and MNS blood groups) at first visit. Due to the high prevalence of partial antigens in this population, genotyping should also be performed if possible.
- In patients with no previous clinically significant alloantibodies, select RBCs matched for the patient’s Rh (D,C,c,E,e) and Kell (K1) antigens.
- If known alloantibodies, select RBCs that are matched for the patient’s Rh (D, C, c, E, e), Kell (K1), Kidd (Jk⁰, Jkᵇ), Duffy (Fy⁰) and S (S,s) antigens, as well as any antigens to which the patient is immunized.
  - Matching for Fyb in sickle cell patients with the Fy(a-b-) phenotype is rarely necessary
- If there is not sufficient time or resources to determine the patient’s phenotype, contact other hospitals that may have transfused the patient previously. (In some regions of Canada, CBS maintains a phenotype registry of patients with sickle cell disease.) In Quebec, phenotype can be obtained from the Transfusion Laboratory by accessing the transfusion summary in the IT system.

ATTENTION

- Notify blood bank immediately about sickle cell disease patients.
- Life-saving transfusion should not be withheld if prophylactically phenotype-matched RBCs are not available.
- Patients with sickle cell disease must be issued a card with their extended phenotype and specificities of any alloantibodies present. The reason for and importance of the card must be clearly explained to the patient.

![Antibody Card](image)
Special Transfusion Requirements (cont’d)

Sickledex®-negative blood

- RBC units which test positive by Sickledex® test are from donors with sickle cell trait (HgbAS). This blood is therefore safe to administer to patients with sickle cell disease, but it will confound post-transfusion measurements of the patient’s HgbS% and should be avoided, if possible.\(^{337}\)

Exchange Transfusion

- Depending upon a patient’s initial Hgb, it may not be possible to achieve a specific target HgbS% by top-up transfusion without exceeding a total Hgb of 100 g/L.
- Exchange transfusion may therefore be required to meet the desired target of HgbS% <30% (HgbA% >70%).
- Ensure patient is euvoletic before initiating an exchange.
- Automated red cell exchange may be available at specialized centres.

Manual/partial exchange:

- A typical protocol (for children, smaller comparable volumes, e.g., 10 mL/kg):\(^{335}\)
  1. Phlebotomize 1st 500 mL of whole blood (for patients who are very anemic at baseline [e.g., Hgb <70 g/L], a top-up transfusion may be required before first phlebotomy)
  2. Bolus 500 mL of 0.9% normal saline
  3. Phlebotomize 2nd 500 mL of whole blood
  4. Transfuse 2 units of RBCs
  5. Repeat as necessary to achieve target HgbS% (typically a 1.5 blood volume exchange is necessary for first treatment; single volume cycle may be adequate for maintenance therapy). Note that for patients starting with Hgb near 100 g/L, step 4 should alternate between transfusion of 1 and 2 units in order to keep total Hgb from exceeding 110 g/L
Primary indications for Transfusion

THERAPEUTIC TRANSFUSION

Aplastic Crisis
- Most commonly due to parvovirus B19 infection, with profound reticulocytopenia.
- Transfusion support may be required if symptomatic anemia, or if Hgb < 50 g/L.
- Due to a compensatory increase in plasma volume, transfuse slowly to avoid volume overload and consider pre-transfusion diuretic.

Sequestration crisis
- Trapping of sickle erythrocytes in splenic sinusoids resulting in massive, painful enlargement of spleen and severe anemia over a period of hours.
- If untreated, sequestration crises cause death from hypovolemic shock/anemia; immediate transfusion often required.
- Post-transfusion hemoglobin levels often higher than expected, suggesting autotransfusion as sequestered RBCs released back into circulation.
- To avoid accidental polycythemia and hyperviscosity, transfuse 1 unit at a time, reassessing Hgb level before administering more.

Pediatrics
In children, consider administering RBCs in smaller than normal aliquots (e.g., 3-5 mL/kg). Often a single transfusion is sufficient to reverse a sequestration crisis.339

ATTENTION
Due to decreased lifespan of sickle RBCs (16-20 days), significant fall in Hgb will occur before the reticulocyte count recovers.338
Less commonly, patients may present with hepatic sequestration crises, characterized by a rapidly enlarging liver accompanied by a decrease in hemoglobin, a rise in reticulocyte count, and a conjugated hyperbilirubinemia. Transfusions should also be administered cautiously due to the risk of autotransfusion and hyperviscosity. Recurrences are common.

Acute chest syndrome

A new infiltrate on CXR in a patient with sickle cell disease, associated with one or more symptoms of fever, cough, sputum production, tachypnea, dyspnea, or new-onset hypoxia.

RBC transfusion in setting of acute chest syndrome results in improved oxygenation.

“Top-up” transfusion to 100 g/L may be sufficient to achieve improved oxygenation.

In some cases progression to exchange transfusion to reduce HgbS to <30% may be necessary.

Some studies have observed equivalent outcomes whether patients treated with exchange transfusion (HgbS% goal of 30%) or top-up transfusion (Hgb goal of 100 g/L).

However, other studies suggest that patients receiving top-up transfusions may progress to requiring exchange.

In absence of evidence from randomized controlled trials, most patients with acute chest syndrome should be transfused, with exchange transfusions reserved for patients with more severe or rapidly progressing disease with concerning symptoms (see yellow box to the right).
Progressive cholestasis
- Syndrome marked by right upper quadrant pain, extreme elevation of bilirubin and alkaline phosphatase, and variable elevation in transaminases.
  - May be accompanied by renal failure, thrombocytopenia, and prolonged coagulation times
  - Without prompt institution of exchange transfusion, patient may develop progressive fulminant liver failure

Acute ischemic stroke or retinal artery occlusion
- Transfusion recommended for adult patients without other obvious stroke etiology (e.g., cardioembolism). 339
- In patients with hemorrhagic stroke secondary to underlying vasculopathy, implementation of regular transfusion support may be beneficial in secondary prevention once the patient has stabilized.

Pediatrics
Transfusion recommended for all pediatric patients with acute ischemic stroke. Within 3 hours of the first unit of transfused RBCs, MCA flow velocity decreases by 20%. 345 Exchange transfusion associated with lower recurrence rate than top-up transfusion. 346
PROPHYLACTIC

Perioperative

- Due to high rates of perioperative complications (e.g., 10% rate of acute chest syndrome), aggressive supportive care and close observation is indicated.\(^{347,348}\)
  - Avoid surgery during vaso-occlusive episodes
  - IV fluids if NPO \(\geq 2\) hours pre-op and continue post-op until oral fluids tolerated
  - Maintain SpO2 >96% and encourage incentive spirometry
  - Avoid hypothermia
  - Favour laparoscopic approaches
  - Post-operative prophylaxis for deep venous thrombosis if immobile >24 hours
  - Aggressive control of pain
  - Early mobilization

- Low-risk procedures: transfusion likely not required.

- Moderate risk procedures: A recent RCT of patients undergoing predominantly moderate-risk surgery established the necessity of pre-operative transfusion: without transfusion, the risk of serious adverse events (predominantly acute chest syndrome) increased from 3% to 33%, with median time to onset 2-3 days post-operatively.\(^{349}\)
  - The transfusion protocol in this study aimed to achieve a HgbS of \(~60\%\) within 10 days of surgery: in patients with a Hgb of \(<90\ g/L\) this was achieved by a top-up transfusion to a Hgb of \(~100\ g/L\), whereas those with a Hgb \(\geq 90\ g/L\) underwent a partial exchange transfusion. A previous RCT in a similar patient population had established that a pre-operative HgbS of \(~60\%\) was no less effective at preventing sickle cell complications than a target HgbS of 30%.\(^{347}\)

- High-risk procedures or serious patient comorbidities (e.g., end-stage renal disease or baseline SpO2\(<90\%\)): a more aggressive pre-operative target HgbS of \(<30\%\) is advisable.

- Pre-operative transfusions (whether top-up or exchange) should be performed within 10 days of the surgical procedure.
### Erythropoietin and Medical Patients

#### Fractionated Blood Products Sickle Cell Disease

**High Stroke Risk**

- In children, transfusion is indicated for secondary prevention of ischemic stroke and for primary prevention in patients with high-risk features (e.g., high middle cerebral artery or internal carotid blood flow by pediatric transcranial ultrasound).
  - In the latter group, maintaining HgbS <30% while keeping total Hgb <120 g/L results in a 92% reduction in stroke incidence.\(^{350}\)

- Children (ages 4-16) without significant cerebral vasculopathy can be safely transitioned to hydroxyurea after 12 months of transfusion if they have no prior history of stroke or TIA [i.e., isolated high Transcranial Doppler (TCD)]. TCD should be performed every 3 months once the switch to hydroxyurea has been done and an immediate restart of transfusion in the case of reversion.\(^{351}\)
  - Transfusion and hydroxyurea need to be overlapped by 4-9 months.\(^{352}\)
  - However, a safe alternative to transfusion has not yet been established in children who have already experienced a stroke, whether it was clinically apparent or silent.\(^{352,353}\)

- Little evidence to guide initiation of transfusions for stroke prophylaxis in adults, or following primary hemorrhagic strokes.
  - The underlying pathophysiology for both thrombotic and hemorrhagic strokes in sickle cell disease is likely the same.\(^{355}\)

</tr>
</tbody>
</table>
Supplemental indications for transfusion

The following conditions should be managed with exchange transfusion for patients who have failed non-transfusion based therapies. The initial therapeutic goal should be HgbS < 30%.

1. Recurrent pain episodes/acute chest syndrome
   - In patients who have failed an adequate trial of hydroxyurea, chronic transfusion support may be considered as means of decreasing recurrence of vaso-occlusive pain episodes or acute chest syndrome.\(^{356,357}\)
   - Transfusion not indicated as treatment of uncomplicated acute vaso-occlusive pain episodes, or for treatment of chronic pain syndromes (e.g., avascular necrosis, osteomyelitis, neuropathic pain).\(^{339,358}\)

2. Priapism
   - Transfusion may be of benefit for episodes lasting >4 hours, unresponsive to aspiration of blood from the corpora cavernosa and irrigation with dilute epinephrine.\(^{359,360}\)

3. Malleolar ulcers
   - Transfusion may speed healing if no response to bed rest, wound care, antibiotics, hyperbaric oxygen.\(^{361}\)

4. Pregnancy\(^{362}\)
   - Although hydroxyurea is contraindicated in pregnancy, the role of transfusion is unclear.
   - A single RCT of transfusion support to maintain the maternal HgbS < 35% did not result in improved fetal outcomes compared to a strategy of transfusing only if Hgb < 60 g/L accompanied by a reticulocyte response of <3%.\(^{357}\) However, maternal sickle cell complications were nonetheless decreased.\(^{362}\)
Transfusion support should be considered for pregnant patients with: A history of frequent vaso-occlusive pain crises
- Chronic renal, pulmonary or hepatic disease
- History of recurrent fetal loss
- Multigestational pregnancy or evidence of chronic fetal distress/intrauterine growth retardation

5. Pulmonary hypertension
- Defined as a resting mean pulmonary pressure (mPAP) on right heart catheterization of \( \geq 25 \text{mmHg} \). Increased tricuspid regurgitant jet velocity (TRV) \( \geq 2.5 \text{m/sec} \) is associated with increased morbidity and mortality but does not necessarily reflect pulmonary arterial hypertension (PAH).
- In patients with TRV of \( >2.5 \text{ m/s} \), NT-pro-BNP >160 pg/ml, or PAH confirmed by right heart catheterization, chronic transfusion therapy should be considered if lack of response (or contraindication) to treatment with hydoxyurea.363
Transfusion Complications

Delayed hemolytic transfusion reactions

- Without prophylactic phenotypic matching, 30% of transfused patients with sickle cell disease will develop alloantibodies, two thirds of them directed towards C, E and K1 antigens.\(^{365}\)
  - Alloimmunization due in part to genetic differences in the antigens expressed on red blood cells in the donor population (primarily Caucasians) and recipients
- 30-50% of antibodies will be undetectable on retesting within the year; patients may be inadvertently challenged with subsequent transfusions, resulting in delayed hemolytic transfusion reactions.\(^{337}\)
- Prophylactic matching for antigens therefore advised when selecting RBCs for sickle cell patients; advance notification of blood bank required.
  - Prophylactic matching decreases the rate of alloimmunization (from 3.0% to 0.5%/unit) but it remains an issue\(^{366}\)
- Due to the high frequency of partial RBC antigens in individuals of African ethnicity, genotyping of patients with sickle cell disease is highly recommended.

Hyperhemolysis\(^{367}\)

- Defined as post-transfusion RBC destruction accompanied by fall in Hgb to below pre-transfusion levels.
  - Hemolytic indices increased from baseline, occasionally accompanied by relative reticulocytopenia\(^{368}\)
  - Acute: occurs less than 7 days after transfusion, often with no new antibodies detectable
  - Delayed: occurs between 1 and 4 weeks following transfusion and often accompanied by new RBC antibodies

\[\text{ATTENTION}\]

Alloimmunized sickle cell patients require antibody card.

\[\text{ATTENTION}\]

Continuing to transfuse a patient with hyperhemolysis may cause worsening of anemia!
Enhanced hemolysis appears to involve both transfused and autologous RBCs, and may be exacerbated by further transfusion of even crossmatch compatible/antigen-negative RBCs.

**Avoid further transfusions, if at all possible:**
- Treat with IVIG 2 g/kg over 2-5 days
- Accompany by high dose steroids (e.g., prednisolone 1 mg/kg/d x 7 days)
- Consider brief course of erythropoietin if relative reticulocytopenia

**Hyperviscosity**
- Sudden onset hypertension during or shortly after transfusion, accompanied by signs of congestive heart failure and profound alterations in mental status, including stupor, coma, seizures, or features of intra-cerebral infarct or hemorrhage.
- Risk increases if Hgb transfused above 100-110 g/L in patients with SCD and HgbS% >25%, particularly if patient dehydrated and hypoxemic.
- May also occur secondary to auto-transfusion following transfusion support of sequestration crises
- Manage with emergency phlebotomy.

**Transfusional iron overload**
- Each transfused unit of RBCs delivers 180 mg of iron.
- Significant iron overload therefore likely after repeated top-up transfusions: may eventually result in hepatic, cardiac or endocrine dysfunction.
- Selecting fresh RBCs (<7 days old) may slow iron loading in chronically transfused patients to a small degree.
- Exchange transfusions can more effectively mitigate or even reverse iron loading.\textsuperscript{371}

- Iron chelation therapy indicated once hepatic iron concentration >7 mg/g dry weight, as assessed by either biopsy or calibrated MRI scan.\textsuperscript{372}
  - This degree of iron loading can be anticipated after the transfusion of more than 70 mg/kg of iron (in adult patients, approximately 20-30 RBC units)
  - Small volume phlebotomy while receiving hydroxyurea may be useful\textsuperscript{351}
  - Iron overload correlates poorly with serum ferritin in sickle cell patients but is likely present if serum ferritin persistently >3,000 ng/mL\textsuperscript{373}

- Iron chelators licensed for use in Canada include deferoxamine, deferasirox and deferiprone.
  - Referral to a centre with expertise in iron chelation therapy advised prior to initiation of treatment

* This cost refers only to the acquisition cost of a unit of RBC. The cost of delivery of a unit of blood to a patient ranges from $522 to $1,183 (US). 374

** This cost refers only to the acquisition cost of plasma. The total cost of plasma is $409.62 per unit or $1,608.37 per patient transfused. 375
Appendix B

Information for Physicians Treating Patients Who Are Jehovah’s Witnesses

- Jehovah’s Witnesses refuse transfusion of allogeneic blood based on their understanding of several Biblical passages, which they view as prohibiting the use of:
  - Whole blood, including predonated autologous blood (prededeposit)
  - Red blood cells
  - White blood cells
  - Platelets
  - Plasma

- Their religious understanding may permit the use of products containing fractions of plasma or cellular components, such as:
  - Cryoprecipitate
  - Clotting factor concentrates
  - Albumin
  - Intravenous immunoglobulin
  - Fibrin glue
  - Autologous blood obtained by cell salvage

- Witness patients will accept most:
  - Surgical and anesthetic procedures promoting conservation
  - Diagnostic and therapeutic procedures (e.g., phlebotomy, angiography)
  - Pharmacological enhancement of hemostasis
  - Pharmacologic stimulation of erythropoiesis (e.g., erythropoietin) that do not contain blood derivatives

- A useful discussion of the position of Jehovah’s Witnesses on blood transfusion and related issues is available.376

- Physicians should discuss the various options with individual patients, as each person must make a personal choice according to their conscience.

- Jehovah’s Witnesses have established a network of Hospital Liaison Committees (HLC) across Canada. On call local HLC members can be contacted through the hospital switchboard or by contacting the Hospital Information Services for Jehovah’s Witnesses. This service is available 24 hours a day at 1-800-265-0327.

**Bloody Easy Blood Administration**

Bloody Easy Blood Administration handbook is ideal for nurses or healthcare professionals administering blood. It provides an overview of blood and blood products, the risks associated with them, and how they should be administered. In addition, it describes the types of transfusion reactions that may occur.

**Bloody Easy Coagulation**

Bloody Easy Coagulation handbook provides practical information on Coagulation. It is designed to enhance the knowledge of physicians, nurses and medical laboratory technologists about the basics of coagulation from laboratory testing to anticoagulant drugs and management of common bleeding disorders.

# Red Blood Cell Pre-Transfusion Checklist

| Alternatives failed or have been ordered? | Anemia investigations completed (e.g., CBC, blood film, ferritin, iron saturation, vitamin B12, reticulocyte count)  
| Iron (oral and IV), vitamin B12, erythropoietin ordered or not indicated |
| Consent? | Patient advised of risks of:  
| TACO 1 in 100  
| Hemolytic reaction 1 in 7,000  
| TRALI 1 in 10,000  
| Major allergic reaction 1 in 40,000  
| Bacterial infection 1 in 250,000 |
| Female under 45? | Order Kell-negative units  
| Inform recipient of the potential risk of transfusion causing hemolytic disease of the newborn in future pregnancies |
| At risk for FATAL transfusion-associated Graft vs. Host Disease? | Order irradiated blood if patient has any history of the following:  
| Hodgkin’s lymphoma  
| Allogeneic or autologous stem cell transplant  
| Ever treated with fludarabine, cladribine, bendamustine, alemtuzumab, anti-thymocyte globulin (ATG)  
| Congenital immunodeficiencies |
| Diuretics? | Does my patient have a history of:  
| Age greater \( \geq \) 70 years  
| Renal dysfunction  
| Left ventricular dysfunction  
| Prior or current CHF  
| Severe euvolemic anemia (hemoglobin <50 g/L)  
| If YES to any of the above: prescribe PO/IV furosemide pre-transfusion (unless currently hypovolemic) |
| Rate and Dose? | Specify rate of infusion (default rate is over 2 hours per unit; inpatients and patients at risk for TACO (need diuretics) infuse over 3-4 hours)  
| Order 1 unit at a time (unless bleeding) |

TACO: Transfusion-Associated Circulatory Overload, TRALI: Transfusion-Related Acute Lung Injury, CHF: Congestive Heart Failure
